Nobility and Gentry.

F late Years, since Gardning and Planting have been in so great esteem, it's observable, that many who have planted Fruit-Trees, have been disappointed in their hopes; for after they have been at the charge of making and planting their Gardens, they then of course expect success, both in their Trees and Fruit; tho' the proper means for both be usually neglected.

We have not only observed these Disappointments, but as much as in us lay, have given our Cautions, especially to Gentlemen that have desired our Opinion: And now out of a true regard to the publick, in respect of Gardning, we communicate to the World these our Observations, which the few, we hope may be of use.

In the first place we think sit to remark that we have gone through the Works of our learned Author with all the exactness we possibly could, abstracting out of each Title, or general Head, all that is useful; and have reduc'd into a proper method, that in which the Original is so prolix and interwoven, that the Reader was rather tir'd than inform'd.

Secondly, the Author tometimes dwells so long upon some one Fruit, that he often passes by another that is equally as good, without so much as giving the least description of it; which Desiciency we have endeavour'd to supply.

To which we shall add something, as to the Obfervations we have made of the Miscarriages and Disappointments that Planters meet with: Which may be

reduc'd into these three heads.

First, the best, or properest sort of Fruit, are not always made choice of to plant, but often the contrary.

Secondly, they are not well manag'd, and order'd

after they are planted.

Thirdly, Some Seasons of late Years have prov'd very bad, and may spoil the Fruits; tho' the greatest Care and Skill that's possible be us'd about them.

First, The best or properest fort of Fruit for each Exposition, are not always made choice of to plant;

but often the contrary.

Gentlemen coming to London at the Seasons of Planeing, and observing often that Bundles of Trees are standing at the Seeds Men Shops, or at least meeting with some of their Printed Catalogues, in which they make large offers of the Sale of all their sorts of Fruit-Trees, Ever-greens, Flowering Shrubs and Roots; but with what Certainty any one may depend upon the Truth of what is offer'd, or what Reason they should have to buy of them rather than of the Gard'ner, we leave them to judge; knowing very well that none of those grow in their Shops.

Another fort of Men there be, that ply about the Exchange and Westminster Hall, some of which never sail of having all sorts of Fruit Trees that you shall want, tho' they have not a Foot of Land: Not but that there are some of those who have Ground of their

own, wherein they raise Trees.

There

There are also those Gentlemen who send directly to a Nursery Man for such and such sorts of Fruit-Trees, not knowing what the sorts are which they send for, but as it is two often seen, one Fruit being call'd by the name of another, they send for such sorts of Fruit which they have tasted under those Names; but it being a mistake, and the Fruits they send for perhaps of the worst Sorts, or not in the least fit for the Exposition allotted them; or it may be instead of the best, they only send for those that are properly fit for baking, this we know, and have sent them the descriptions of the very same Fruits they have sent for thro' their Mistake, which hath soon caused them to change their Opinion, & forth with make choice of those forts that have been more proper for them.

As for Instance, There came a Letter from a Perfon of Honour in Scotland, to send him the several sorts of Fruit Trees mention'd in his Catalogue, wherein were twelve sorts of Peaches, of which six were such as ripen with us very late, as Malecotoon Peach, which is not worth any ones planting, and some others of late kinds; whereas we find by experience that those latter Peaches hardly even ripen here; and what can be imagin'd will the success of them be, when they are planted to far North 2 most certain that Noble Lord would never have sent for those sorts, had his Lordship had the least knowledge of them.

Now it may be some of those sorts of late ripe Fruit, that are proper neither for the Soil nor Exposure, are sent according to their order, and Planted, and very often the space of time between the Planting and their Bearing may be some Years, in which time they have forgot what Trees they sent for; but it may be the Trees thrive very well, and there is great expectation of some fine Fruit, but when the Fruit is tipe, and at its sull Maturity, all their expectations are srustrated; for perhaps a hash gritty choaky

Pear, a late watery Peach, or a fower Plum; then the Nursery-Man is presently slav'd and condemn'd for a cheating Knave, for sending them such sorts of bad Fruit, when at the same time they were the very same

forts they fent for:

There is also a fort of Men who call themselves Gardners, and of them not a few, who having wrought at labouring work at the new making of some Ground or in a Garden, where a great many Hands are employ'd; and after the young Beginner hath exercised the Spade and the Barrow for twelve Months or there-abouts, he then puts on an Apron, sets up for a professed Gard'ner, and a place he must have; he hears some honest Country Gentleman is in London, and wants a Gard'ner; he goes to him, and tells him his Story of what great matters he is capable of, and that he hath been at the new making of such a Ground, and such agreat piece of Work he manag'd, and it may be he gets a favourable Letter, or at lest some recommendation from some of those Sellers of Trees before mention'd; so then he is hir'd. and his Mafter tells him he has brought to Town with him a Note of some Fruit Trees that he shall want, and asks him if he knows the best forts, (his Answer is, he kens them reet weel) and has so much Impudence as to name some fort or other, right or wrong.

Now this List is sent to the Nursery Man, and if he makes any Scruple of sending the same sorts, it's judg'd he's loth to send out his best Fruits, for the Gentleman thinks that his Gard'ner hath all the reason in the World to make choice of the best Sorts of Fruit and therefore have them he will; now if the Nursery Man hath not these sorts, he is forced to buy them: So that in this, and other like Cases, a Nursery-Man is oblig'd to raise a supply of some very indifferent, or bad sorts of Fruit-Trees to serve these Purposes. This is sufficient, without medling any further, to demonstrate how far this Gentleman is

impos'd

impos'd upon, even at the first step; and this we do affirm to be true of our own knowledge, those Men having wrought with us; and of those Northern Lads much is owing to their Impudence.

Secondly, That Fruit-Trees are not well order'd

and manag'd after their being Planted.

There be some Gentlemen who send for the best sorts of Fruit-Trees from a Nursery-Man, or Gardner, and accordingly the Trees are sent, and perhaps the Directions for placing them against the Walls which they properly require, and are afterwards Planted but let us inquire how they are planted and order'd.

It may be those Trees that are sentare planted against some old Walls, where other Trees have dyed the Year before; now what is done in this case, why Holes are made just where the other Trees stood, and the Tree Planted now the odds is more than ten to one, whether

these Trees ever come to answer expectation.

Or if it be a new Wall, then it may be a Trench is dug in clay or Gravel, according as the Ground is, of two or three Foot wide, and of a proportionable depth, so that the Borders are fill'd up with good Earth, and there the Trees are so planted, that by that time the Trees come to bear, their Roots have got to the extent of the good Earth, and then return back again, by which the Fruit becomes small, bad, and of no relish.

But in those places where the Borders are made of a proper Depth and Wideh, and with good Earth, and the Trees carefully planted, it may be instead of the Trees being carefully headed at the most proper time, they are not beaded at all, but stand with their Heads on all Summer; or if they are, it may be instead of being carefully water'd all Summer, the Borders are full of Weeds, or if clear from Weeds, then it may be a Crop of Pease and Beans are sown and planted upon them; or if a Garden of Pleasure, then the Borders

are fill'd up with the several varieties of great growing Flowers, which suck the nourishment from the Trees,

and utterly destroy all good Fruits.

There might be many more Instances inserted of this Nature, of all which we have been Eye Witnesses, and two often seen these neglects in the several Plantations we have seen manag'd, without mentioning the great abuse which Fruit Trees suffer for want of being well prun'd, and the Fruits carefully pick'd, and other neglects of this Nature; for in truth it's rare to see these works well perform'd.

Thirdly, That some Seasons of late Years have proved very bad, and may have spoiled the Fruits, tho' the greatest Care and Skill had been us'd about them

that was possible.

As to the difficulty of the Seasons, if we suppose the best Fruit Trees to be planted and manag'd with the greatest Care and Diligence, the Ground first of all well prepar'd, and Fruit Trees budded or grafted on such Stocks as are most proper to the nature of the Ground, and the several kinds planted against the Walls properly where they should be, and afterwards skilfully prun'd, and as often as is needful, the superfluous Fruit pick'd off, and no more left on each Tree, than it can well being to perfection, to be fair and good, when all these directions are duly observ'd, yet by reason of the badness of Seasons, by Cold, or too much Rain, many of the Fruit often prove watery, insipid, and worth little or nothing.

These following Fruits are known to be the best of their Kinds, and when well manag'd, and the Scason favourable, there is none that do exceed them,

23%

Peaches.	Minion. White Red Magdalen. Montabon. Belchevereuse. Burdine.
/*	Admirable. Old Newington.
The state of the state of	Red Roman,
	Violet Hastive. Brinion Rond.
	Virgoulee.
	Le Chaffery. Ambret.
	St. Germine.
Pears.	Espine.
1	Crasseine. Colmar.
-	La Marquiss.
Ţ.	Buree.
1	Vert Longue.

These several Fruit-Trees we have had growing in our own Plantation at Brumpton Park, and others, where no Skill, Cost, or Pains have been wanting, yet we do affirm that in some bad Seasons several of the aforemention'd Fruits have had little or no Relish or Flavour in them, nay insomuch that if our selves and others had not gather'd good Fruit from the same Trees in more favourable Summers before, and knew them to be the true kinds, one might have been deceiv'd, and if a stranger had tasted the Fruit both in a good and a bad Season, he would not have believed that the same Trees could produce so different Fruits.

Now if it be so, that in some bad Seasons the Fruit proves very indifferent, tho' it meet with the best

ulag

a 4

usage. What can be said to those Men who expect every year to have the best of Fruit, without taking due Regard to the managing of them; who in Planting of them, do not consider to plant Peaches, Pears, &c. to the several Aspects, against the Walls, which they do properly require? So that instead of Planting them against a South Wall, they are often planted against a North, North East, or North West Wall?

Again, others hearing that the aforementioned Pears are the very best sorts, they many times send for them, and plant them to be Dwarfs, and not against a Wall; whereby when they come to bear, the Fruit generally comes not to its due Persection, whereupon the Gard'ner that sold the Trees is blam'd, and counted a Rogue for selling them such bad Kinds.

But whereas the most Ingenious Monsieur De la Dnintiny says, that he has tasted above 300 several sorts of Pears, different one from another, without finding above 30 sorts that are Excellent; he likewise inserts, that great Allowances must be made to the fickleness of Seasons, of which we are not the Masters; as allo of the Diversity of Soyls and Climates, which is almost infinite, and to the Nature of the Stock of the Tree, and lastly to the Manner or Figure in which the several Trees grow and produce.

They are all points that require a great deal of Consideration, and very quick Sense to ballance the Opinion of those that would judge of them. There are sometimes ill Pears among the Virgoulees, Le Chasseries, Ambretts, and Thorn Pears, &c. and but scurvy Peaches among the Minions, Magdalens, Violets, Admirables, &c. and bad Plums among the Perdrigons, some bad Grapes among the Muscats, and bad

Figs among those that are most esteem'd.

This

This may perhaps aftonish some Curious Person but the in a certain fort of good Fruit there may be some descrive, yet it follows not from hence that the whole Kind should be rejected; for a Fruit may prove ill one Year, or in such certain Expositions, which may have appear'd good several Years before; so on the other hand, that Fruit which was good this Year, was not to be endur'd for some preceding Years.

Now to prevent as much as in us lies, and put a stop to these grand Disorders for the suture, and to direct our Nobility and Gentry into a true Method, how to prepare the Earth, and make their Ground sit for planting, and how to have good Trees, whereby they may have real Cause to rejoice in the Event.

Take the following Rules, with what you'll meet with in the Abridgement, which may be sufficient

Directions for all young Planters.

1st. As to the preparing and making your Ground

fit for planting.

In all the Plantations that we have had to do with or have observed, we have found by Experience, That when young Trees are planted in the fame Earth that others have died in, they seldom or never succeed well in it; so that in this Case, the only and best way will be to take out all the old, wormout, or exhausted Earth, about 4, 5, or 6 Foot Diameter, and of a proportionable Depth, that is where you design to Plant your Tree, and take some good fresh Earth to fill the hole up: The best Earth for this Use is a fort of a rich landy Loam, which may be taken near the Surface of some rich Pasture Ground where Cattle have been fed or fother'd, or of Sme rich Sheep Walk, where there is a Depth of Earth; and if it is mix'd with a little old Mellon Earth, or the like, it may do well, or Cow or Horfes Dung may likewise do well if it is quite rotten, so as to be like Earth; but of this a small Quantity, as one part in four or five, and so rotten that it may not

be discern'd to be Dung, but Earth.

This lort of Earth ought to be prepar'd, ond to lie some time on a heap before planting, and if you have Conveniency, to keep it from great Gluss of Wet, so that when you come to use it, it may be dry, and being well wrought and turn'd over, it becomes fine, and in using fills up the Vacancies between the Roots.

This Earth is of great use where Ground cannot be brought into a fit condition for planting, by reason of its being over moist, and will not admit of being well wrought, till such time as the Season for planting will be over, and sometimes in a very dry Spring when the Work is undertaken late; so that the Earth of it self in the Ground, will not admit of planting, and having a Stock of this fort of Earth so well prepared and ordered, the planting may very well go on, and by which a Year's time is sav'd: For having to each Tree only so much of this Earth to cover the Roots of the Tree, and fix him so that he may stand firm, the rest may be done at a time when the Weather will better admit of it.

After these Trees are well planted in this Earth, and having good half-rotten Dung near at hand, lay on a Coat of about three or four Inches thick, afterwards laying on a sprinkling of Earth of about an Inch thick, and above that lay on Fern at old Straw five or six Inches thick or thereabouts, and two or three Foot every way from the Stem of the Tree, then lay on a few great Stones, which will be of use to keep the Wind from blowing off the Fern or Straw.

This Coat of Dung and Straw will be of great Benefit to the Roots of the Trees, keeping them warm in the Winter from the violent Frosts, and cool in Summer from extreme Heats; and as time

and

and Wether wasts the Dung, Fern or Straw, it renders it very agreeable to the Roots of the Trees, or

Plants against a Wall.

After this is perform'd, if Wall Trees, let the Principal Branch of them be nail'd to the Wall, to keep them from being shaken by the Wind, for 'tis a great Annoyance to all Fruit-Trees and others, to be so shaken en; especially when they have struck young Roots, by breaking them off, which is a great Hindrance to their Progress in growing, and often causes their dying.

Also in all Standard Fruit Trees and others, if this Method of fresh Earth be used in planting, and after being well planted, to be stak'd and tied so as the Wind or Cattle do not anoy them, the Owners will

reap a fatisfactory Benefit.

If your Trees are not headed, or at least so low as they should be when they are planted, then observe, that as soon as the Buds begin to swell so as you can be able to discern which are most proper to serve for the use of filling up the Wall, then head your Trees, cutting them within six or nine Inches of the budding or grassing Place, more or less, according as the Tree is surnished with Buds; but be sure to hold the Tree sast, so as the Roots may not be moved.

In performing this Work of heading of those Trees at the Spring: it ought to be done with a particular Care.

Now supposing these Trees are planting according to all the Directions before mentioned; it follows not from thence, but that they may still lie under farther Inconveniencies, if due Care be not taken to water them when they require it, to keep the Borders, Divisions, or other Places clean from Weeds: For in some space of Years there ought not to be any thing suffer'd to grow within five or six Foot of the Root of the Tree, to suck the least Nourishment from it.

And they must be also well secur'd from the injuries of Cattle, &c.

For we rather chuse to advise all persons not to Plane at all, than not to take proper methods whereby their Trees may succeed; for it can never be pleafing to see a stunted Tree, or a Plantation not thrive, and we are most certain it can be no satisfaction or Credit to any honest Nursery man or Gardner, to see or hear of such Miscarriages.

To be furnish'd with good Trees.

Enquire out an able Nursery-man, or Gardner of good repute, give him an account of the Aspects of your Walls which you design to plant, and the height of them.

Also let him have the particular length of each Wall, &c. in yards or Feet, and what fort of Earth your Ground does most incline to, whether hot and dry, or cold and moist, &c.

This Nursery man must regulate and proportion the whole Plantation with Trees proper for the several Aspects and nature of the Soil, as also for all Dwarfs, Standards, or half Standards, which shall be thought necessary.

But perhaps a Gentleman has a Plantation already, yet wants a few more Trees for some vacant places; herein the Nursery Man should be likewise inform'd what plenty of choice Fruits you have already.

As for Example.

If you are pretty well flor'd with the Buree Pear, which indeed is one of the best forts of Fruit in its proper Season, and so likewise for any other choice forts, you may chuse rather to be supply'd with some other sorts generally allow'd to be good.

But herein be not over-fond of infinite varieties of Fruit, for the most knowing Men in Fruit-Trees, rather content themselves with a few good sorts, than

trouble

the Nobility and Gentry. xiii

trouble themselves farther, where they are sure to find little or no tatisfaction:

It may not be amiss to give a Word or two of Directions for planting an entire Collection of Fruit.

Supposethen that you have Walls and ground enough to plant a whole Collection, herein it will be mainly necessary so to regulate the matter that you may be supply'd with Fruit at all times of the Year: In order to which its requisite to have Fruit-Trees suitable to each Season; as, first to Summer, next for Autumn, and next to them the first Winter Fruits, such as are eatable in November and December; and lastly, the late Winter Pears, as the Bon Chretien Double, &c. which will continue good a long time, even till April, if carefully gather'd and look'd after, and will then be excellent.

As for Summer, tho' there be several excellent perfum'd Pears, as also of Peaches in July and August, yet they soon perish.

Also in Autumn, to have too many Buree and Bergamot, (tho' the best in that season) will not be convenient. but to have other Fruits sollow them succes-

fively ..

We are of opinion that high Wolls will do best tobe planted with the choicest forts of Winter Pears, for the advantage which is reap'd from them is very great; the Fruit usually keeps very long, if gather'd in a proper Season, and discreetly dispos'd of afterwards; and some sorts of them will make a lovely appearance at your Table for six Weeks or two Months together; also another great Benefit is, that they may be conveyed with safety from the Country to London, or elsewhere, as there shall be occasion.

It is to be noted, that the there Directions that are given in sending the length and heighth of the Walls, together with their several Aspects, and nature of the Ground, to a Nursery-man or Gardner, is

Advertisement, &c.

xiv

only for those Noble-men and others, that have not had the knowledge of Fruie, whereby to make the most judicious choice themselves; but for those that have had that knowledge, or at least have a sufficient Gardner, it's supposed that they may send their order for such and such sorts of Fruie, being able to judge of what sorts they most stand in need of, or at least that are most suitable to their Pallates.

SOME

An Advertisement of J. Evelyn, Esq; to the Folio Edition of Monsieur La Quintinye.

M. J. P. H.

Cannot conceive but it must needs be a very acceptable Advertitement, and of Universal Concern to all Noble men, and Persons of Quality, lovers of Gardens, and Improvers of Plantations (of all Diversions and Employments the most Natural, Useful, innocent and Agreeable) at what Distance soever (from a Place of so easy and speedy Correspondence, and which is so near this great City) to give this Notice.

That of all I have hitherto feen, either at Home or Abroad; or found by Reading many Books publish'd on this Subject, pretending to speak of Nurseries and Plantations for store and variety; Directions for the Designing (or as they term it) the Skilful Making, Plotting, Laying-out, and Disposing of a Ground to the best Advantage: In a word, for whatsoever were desireable for the Furniture of such a Ground, with the most excellent and Warrantable Fruit (I say Warrantable; because it is peculiarly due to their honest and so rarely to be met with elsewhere) and Industry. other Accessories to Gardens of all Denominations, as in that Vast, ample Collection which I have lately seen, and well consider'd at Brompton Park near Kenfington: The very fight of which alone, gives an Idea of something that is greater than I can well exa press, without an ennumeration of Particulars; and of the exceeding Industry, Method and Address of those who have undertaken, and Cultivated it for publick Use: I mean Mr. George London (chief Gardner to their Majesties) and his Associate Mr. Henry Wise: For I have long observed (from the daily practice, and effects of the laudable Industry of these two Partners) that they have not

made

An Advertisement of J. Evelyn, Esq;

made Gain the only mark of their Pains; But with Extraordinary, and rare Industry, endeavour'd to improve themselves in the Mysteries of their Profession, from the great Advantages, and now long Experience they have had, in being Employ'd in most of the celebrated Gardens and Plantations which this Nation abounds in; besides what they have learn'd Abroad, where Horticulture is in highest Reputation.

I find they not only understand the Nature and Genius of the several Soils; but their usual Insurations, proper Remedies, Composts and Applications to Reinvigorate exhausted Mould; sweeten the soul and tainted, and reduce the Sower, Harsh, Stuborn and Dry, or over moist and diluted Eath, to its genuine Temper and Constitution; and what Aspects, and Situations are proper for the several sorts of Mural, Standard, Dwarf, and other Fruit trees.

They have made Observations, and given me a Specimen of that long (but hitherto) wanting particular, of Discriminating the several kinds of Fruits, by their Characteristical Notes, from a long, and Critical observation of the Leaf, 'Tast, Colour, and other distinguishing Qualities: So as one skall not be imposed upon with Fruits of Several Names; when as in truth, there is but one due to them. For instance, in Pears alone, a Gentleman in the Country fends to the Nurseries for the Liver Blanch, Pignigny de chouille, Rattau blanc, &c. the English St. Gilbert, Cranbourn Pears (and several other names) when a'l this while, they are no other than the well known Cadillac. The same also hap'ning in Peache, Apples, Plums, Cherries, and other Fruit; for want of an accurate examination (by comparing of their Taste, and those other Indications I have mentioned) For which Gentlemen complain (and not without cause) that the Nursery-men abuse them; when 'tis their Ignorance, or the Exotic Name of which they are fo fund.

I find they have likewise apply'd themselves to assain a sufficient Moslery in Linus and Figures for general design,

An Advertisement of J. Evelyn, Esq;

design, and expeditious Methods for casting and leveling of Grounds; and to bring them into the most apt Form they are capable of; which requires a particular Address, and to determine the best Proportions of Walks and Avenues, Stras, Centers, &c suitable to the lengths; and how, and with what materials, whether Gravel, Carpet, Sc. to be layed.

They have a numerous Collection of the best Designs, and I perceive are able of themselves to Draw, and contrive other, applicable to the places, when busic Works, and Patterns of Imbroidery for the Coronary and Flower Gardens are proper or desired. And where Fountains, Statues, Vasas, Dials, and other decorations of Magnistance are to be plac'd with most advantage.

To this add a plentiful and choice Collection of Orange-trees, Limon, Mertil, Bayes, Jassmines, and all other Rarities, and Exotics, requiring the Conservatory; after they have embellish't their proper stations abroad during the Summer, and for continuing a no less ornament

in the Green-House during Winter.

They have a very brave and noble Assembly of the Flowery and other Trees; Perennial and variegated EvertGreens and shrubs, bardy, and sittest for our Climate; and understand what best to plant the bumble Boscage, Wilderness, or taller Groves with: where, and how to dispose, and govern them according as Ground, and situation of the place requires both for shelter and ornament. For which purpose (and for Walks and Avenues) they have store of Elms, Limes, Platans, Constantinople-Chesnuts, Black Cherrytrees, &c.

Ner are they, I perceive, less knowing in that most useful (though less pompous part of Horticulture) the Potagere, Meloniere, Culinarie Garden: Where they should most properly be placed for the use of the Family; how to be planted, furnished and Cultivated so as to afford great pleasure to the Eye, as well as prosit to the Master. And they have also Seeds, Bulbs,

Roots,

'An Advertisement of J. Evelyn, Esq;

Roots, Slips, for the Flowry Garden, and Shew how

they ought to be order'd and maintain'd.

Lastly, I might super-add, the great number of Crounds and Gardens of Noble-men and Persons of Quality, which they have made planted ab Origine, and are still under their Care and inspection (though at Considerable Distances) and how exceedingly they prosper, to justifie what I have said in their behalf.

And as for the Nursery part in Voucher, and to make good what I have said on that particular, one needs no more than take a Walk to Brompton Park (upon a fair Morning) to behold, and admire what a Magazine these Industrious Men have provided, sit for age, and Choice in their several Classes; and all within one Inclosure: Such an Assembly I believe, as is no where else to be met with in this Kingdom, nor in any other that I know of.

I cannot therefore ferbear to Publish (after all the Encomiums of this great Work of Moun so de la Quintinye, which I confess are very just) what we can, and are able to perform in this part of Agriculture; and have some Amounties and advantages peculiar to our own, which neither France, nor any other Country can attain 20; and is much due to the Industry of Mr. London and Mr. Wise, and to such as shall imitate their Laudable Ondertaking.

Be this then for their Encouragement, and to gratific fuch as may need or require their Assistance.

From the restricted to

J. EVELYN.

SOME

RULES

FOR THE

Defence of GARDENS,

AND

Securing of large Plantations from turbulent and blasting Winds.

With Instructions touching Espalliers, or places of Shelter for the preserving of tender Greens and Plants.

T's strange to consider to what a vast Persection we in this Island are arrived in a few years in many laudable Arts, but especially in Gard'ning; wherein we are at present very little Inserior either to the Italian, French, or Flemming. But that which renders our Gardens and Plantations less successful than theirs, is judg'd to proceed, as certainly it does, from the variableness of our Climate, compared with that of the more Southern Continent: For those that are upon Terra Firma do observe, that tho' their Winters be severe, and many times sharper than ours, yet when that is past, usually moderate and comfortable Weather succeeds all the Summer after. But we here in

England

xvi Rules for the defence of Gardens.

England find it quite otherwise, Experience making it too often appear, what sudden Alterations we have of Weather through most parts of the Year, as from hot to cold, from calm and ferene, to ftormy, turbulent, and sharp; and all this sometimes in a very short space of time. This indeeed does too often frustrate our Labour and Industry, so that we are under a necessity of contriving a timely Remedy, (as far as lies in our Power) to preserve our Gardens against the encounters of this destructive Enemy: Especially since our Predeceffors in Gard'ning, nay even the most eminent Pra-Ctitioners therein, as well as several ingenious Gentlemen, who being well skill'd in art, and have written of Gard'ning, have wholly omitted, or too much neglected is, contenting themselves only with making a Brick or Stone Wall about their Garden; conceiving when that is done, that they are sufficiently provided with a secure defence. Which was also the opinion of that time, in which the Author of the Complete Gard'ner made it his Practice to plant under all thôse several Parallel Walls at the Royal Potagerie at Versailles, which is near twenty Years since; upon the Plant of which Garden, with its Walls and Scituations, some Observations were made in April last, viz. 1698. by G. L. which are as follows.

In all the Divisions of the Parallel Walls, where they were placed closest, the Peaches and Nectarines were almost wholly gone off from the Wall, especially those near the Door-way, and also in those Quarters where the Parallel Walls were set in obtuse Angles, one might observe that all the Branches of the Trees were gone off within three or four Foot of the Ground, some were half gone, and great numbers of whole Trees were entirely gone; all which was the mischievous effects of Eddy-Winds: So that if a strict calculation was made of all those Peach Trees, and Nectarines which Monsieur La Quintinie planted, and

had in Persection about twelve Years since, one would not find sorty good Peach Trees in all that great Design for Wall Fruit-Trees, whereas in his Book he describes some hundreds of Trees for that purpose.

'Tis farther observable that those Trees which miscarryed most, were such as grew upon the South West Walls.

And that in the great Square of that Garden the Trees have not been so much destroy'd as in the little Squares, for which this reason may be assign'd, viz. Their allowing several of those Trees which were design'd, for Dwarfs, to run up into tall Heads for Standards, which do in part break off the Winds from those tender Trees which are against the Walls.

'Tis also observeable that this Plantation, which in all probability was intended for one of the finest in Europe, is now in the Year 1698, reduced from that Protperity it enjoy'd in the Year 1686, even to such a degree of destruction, that not one part in three of those Trees can be found in Perfection, and even these are either Pears, Plums and fine Cherry-Trees. They have indeed new planted most of their Walls with Peach Trees and Nectarines; some Plantations are also made on the outside to break off the Winds, and for the same reason they have permitted several of their Dmarss to run up for Standards in the great Squares, from the shelter of which they expect to succeed in retrieving the former prosperity of their Plantation.

These observations I thought fit to insert, as falling naturally in, to confirm the Rules of our present Discourses

Some may question why we must now have these works of Espaliers here in England, more than their Foresathers had, who found it sufficient to have Gardens encompass'd with good Walls against which several Fruit-Trees were planted, which by experience they found to come to good Persection; as for instance in the Scituations of some old Monasteries?

To this 'cis answer'd:

We know by experience, that when we have been invited to several places to give our Advice, in order to the altering, or new making of some Designs for the Ornament of Gentlemens Seats, by making regular Lines for Walls, or for Standard Fruit Trees, we have found some of those Scientisms have been formerly noted to be places excellent for good Fruits, &c. for which several Reasons may be given.

First, We have observed that most of those places have been scituated in an excellent Soil, on the South declivity of a Hill, a fine River on the South of that, secured very well from North, North-East, and Northwest Winds by high Trees of several kinds, and some Trees also on the South East, and South West; so that the whole Scituation hath been secured from violent

Blights of the Winds. 11

In these old Sciruations we have observed, that there had been very good Trees against the Walls; more particularly in one place we observed an old Body of a Newington Peach, whose Trunk was like an old decayed Willow, the Wall was of Brick, and near sourteen soot high above ground, the Tree had spread from the Scem twenty Foot on each side, which was near sive bundred and sixty superficial Feet; this Tree was planted in the Year 1633, and the old Body was taken up with a few live Branches in the Year 1682, which was near fifty Years old. It is very rare to find a Tree in any good Condition, at this time, half that Age.

We have also observed, that at some of those old Monasteries, and Sears so well sheltered from the Winds, and that have been noted places for plenty of good Fruit and early ripe, that by erecting some new Buildings, or the decayedness of the Trees, that has caused them to be taken down, has soon made an alteration, insomuch that those places have had their full share of the Blights, exactly

with

with other places, if not worse; neither did the Fruie after that come so early ripe as formerly, for where care hath been taken, that large Plantations should grow on the outward Bounds of the Garden, the Benefit of them is very great, besides the breaking off the cold blighting Winds; for the glowing heat of the Sun, in all those places so well defended, causes both Plants to slourist, and Fruie more early to ripen.

This being so, we suppose it needless to add how highly necessary it will be to find out some better security for our Gardens and Plantations, so far as is possible: For the effecting therefore of which, we shall

lay down some short Rules and Directions.

First, for securing of Gardens and Plantations.

Second, to make a defence for fecuring of Orange-Trees, Limons, Myrtles, and other tender exotick Greens and Plants in the SummerS eason.

In the first place to make a general security for a whole Garden or Planeation, it will be necessary to plant Trees for desence thereof, some distance without the utmost Bounds or Walls, in such manner as is hereaster specified: The Lines of Trees for this purpose, may be planted in two or three Rows; its convenient that they be planted pretty thick, considering the use that they are for. And in Planting of them, after the first Line is planted, let the second Line be planted in such order that every three Trees may make an Æquilateral Triangle, that so the first Range may be closed by the second, after which a third Line may be planted which may bear the same proportion to the second, as the second does to the first; in this manners

b 2 Three

Three Rows of Trees Planted in this order, will be found to be of extraordinary use; and if it may be done with conveniency, let these Ranges encompass the whole Plantation or Gardens. This method of planting is much better than at right Angles, for several reasons.

The distance of Planting them may be from eighteen or twenty Foot, to 25 Foot asunder.

These several sorts of Trees are fit for this use.

Elms, Durch, Witch, English.
Abealls.
Beach.
Oak.
Lyme.
Siccamore.
Pine.
Scotch Fir.

But of all these the three sorts of Elms and Lymes, are to be preserr'd, if to be obtain'd with conveniency; tho' if the Rules hereaster laid down be well observ'd and put in practice, the Firs and Pines may be of great use.

What Trees foever are imploy'd for this use, let them be strong, and the larger the better, for hereby they will the sooner answer the design propos'd; in transplanting of them, let them be taken out of their natural Earth or Abode with a great deal of care, and with as much of their Root to them as is possible, and moderately prun'd and well planted, but not too deep if the Ground incline to Moissure, for hereby, many Trees are spoil'd; we rather advise all Persons to plant rather shallow than deep, and therein they can hardly err. After they are planted, let them be very well stak'd, that they may have strength to withstand the strong Winds, 'till they have taken Root sufficient to subsist of themselves; in their growing up they must be taken care of every Year, and well water'd on all Occasions.

Their Head should not be too tall at their first Planting, for when they are so, they will require abundance of trouble in staking of them firmly.

It will be proper for all Persons that hereafter shall make Garden or Plantations, as soon as they have measured and laid out the Bounds thereof, to begin to plant these Rows of Trees in the aforesaid method, even before they go about the making of their Gardens, that no time may be lost, and that they may be a serviceable Defence with as much speed as may be.

Pines, and all forts of Firs, look very well when Planted in this manner, and are ofgreat usefulness in breaking off Winds from the inward Plantation; they make a very fine tow'ring show in the Winter Season, when all other Trees and Places lock rusty; likewise if they are planted on a rising Ground so as to be seen at any great distance, they look very noble and pro-

per for all magnificent Seats.

But to effect this, they must be procured out of some Nursery, their Size to be from two Foot to three or sour Foot high, let them be planted in some place in the Garden, or some necessary place set apart for that purpose, in order to be afterwards transplanted out, where its design'd they shall stand, but first let them come to be seven, eight, or nine Foot high; after which they must be taken up with almost all their Roots, and as much Earth about them, as two,

or four Men can carry, with each Tree in a Hand-Barrow, this Earth will be a great means to fix them where they are to be planted, that they may thrive better, and more firmly withstand the violence of the Winds; and by being remov'd in this manner, they suffer very little Damage as to hind'ring their growth.

This way of Planting is of excellent use and benefit to all such Persons as intend to make large Plantations of Firs and Pines for Avenues, Views, or Walks of Shade, or the like, in Pasture Grounds, Parks, or other grasting Grounds where Cattle come, or to bound their Garden by planting one, two, or three Lines of these sorts of Trees without the Bounds of the Garden. But of these the Silver Fir is a noble Tree tho' the other does very well.

This method being follow'd, it may be accomplished with a great deal of ease, but if they should be planted out at two Foot and half, or three, or sour Foot high, in Parks or other Places where Cattle come; its a very hard matter to secure them, or to keep the Ground loose, and in such order as the said

young Trees require.

As for those which are planted out of the larger fize, after they have stood three or four Years after planting, they will be out of the reach of Cattle from

injuring their Boughs.

The nature of some of those Trees such, that they do not shoot away free and strong 'sill they come to be about three or four Foot high, after which there are few Forest Trees that out strip them in growth,

when well manag'd.

We enlarge the more on these Trees, by reason of their Nobleness, there being hardly any body that has undertaken any thing of this kind, that ever repented them of their Charge and Trouble, if a right method were taken in ordering of them; they will for the beforemention'd use be the most proper and useful of any.

We

We have often observ'd about some Noblemen's Seats, what vast Charges they are sometimes at in levelling and putting their Ground in order for Views, Avenues, or some private walks of Shade, and after they have been at all this expence, perhaps the Ground is planted with Ash, Walnuts, Abeals, or such like ill growing Trees.

Whereas if the Rules before fet down had been well obterv'd, then those fine growing Trees would psrhaps have been as cheap or cheaper, since in the beauty and fineness of the Trees, there is no compa-

rison to be made.

The Greens aforesaid do very much excelall those that shed their Leaves, by reason they continue the same all the Winter, besides they will aspire to a great height, become beautiful Trees, and of long duration.

It remains now to lay down some Rule: and Directions for making Espallier Hedges, or places of desence for securing of Oranges, Myrtles, and other tender Greens and Planes from malevolent Winds in the Sum-

mer Season.

By reason of the want of a security for these tender Greens and Planes (when exposed abroad in Summer) we too often find the ill effects, and that many times they suffer more prejudice in twelve Hours time, than they can afterwards recover in two Years. And indeed hitherto there have bin but few that shelter them at all in Summer, the event whereof has been, that what Strength they get one Summer they lose the next, and hereby are deprived of the opportunity of making any strong and vigorous Progress.

But if there is occasion for the use of these Espalliers soon, that is the first or second Year after their being Planted, then must there be a substantial Frame of Wood made of seven, eight, or nine Foot high, the distances of the Posts asunder to be according to the length of the Rails which is commonly about eight

or nine foot long, and of an Espalier Frame of eight Foot high from the top surface of the Ground, in which heighth of eight Foot, there may be 6 Rails, each Rail being about 17 Inches asunder, and the same Distance from the Ground, as you may see here prescrib'd.

These being the form of the Espaliers, every one may add to the Bigness, Strength, or Beauty of it as he thinks fir.

If these Espaliers be us'd in a Country where Timber is plenty, and in a Garden or part of a Garden where it is not expected that the Wood work should appear fine the first and second Year, then this Frame may be made and set up of Poles cut out of the Woods, of Ash, or the like sort of Wood that will split, provided it be strong. The higher you plant

your Trees, the stronger the Posts must be; and care must be taken that the Frame be set upright, and

straight.

But it is to be observ'd, that in all the several sizes of Espaliers, the Trees or Plants to be there Planted ought to be handsome bred Plants, and such as are turnisht with side Boughs, that they may be tyed to the Rails, in order to cause the Espallier to thicken the sooner; and it is to be Noted, that where these Espalliers are made in the middle of a Garden, that Lyme-Trees are rather more proper for this use, than Elms, by reason that the Roots of Elm-Trees run over a great deal of Ground, and injure most Trees, or Plants that grow near them, which the Lyme-Tree does not near so much.

The several sorts of Trees that this Espallier may be

made of, are these.

Dutch. Elms Witch, English. Lyme. Horn-beam Beach. Maple. Alder. White thorn. Privet. Spruce Fir. Pines and Scotch Firs. Laurel. Holly. Yew. Apple: Pear.

Any of these sorts, if ingeniously ordered and regulated, as they ought to be, will answer the end Design'd.

Aa

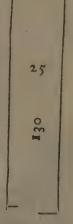

As to the Form thereof let it be an Oblong, or long Square, like that represented in the Margent; and in laying out of its Dimensions on the Ground, let the two longest parallel sides run North and South, or thereabour.

The largeness and extent thereof must be regulated and proportion'd, according to the number of tender Greens and Plants, which it's design'd to contain, always allowing proper distances in placing of them, and for Allies, that there may be conveniency of coming to Water and view them on all Occasions.

30

Now let it be consider'd where this Espallier ought to be placed, and if it may be conveniently done, let it be at no very great distance from the Green-House, (where they stand in Winter) for the better removing of them forward and backward: But if it cannot be so ordered without obstructing of the decent View of the Garden or Buildings, then place it in some other convenient part of the Garden.

The next thing is to begin to make this Espallier, in order to which, after its Dimensions are markt out, make a Border answerable thereto, which should

be eight Foot wide, and well Trencht, two Foot and a half, or three Foot deep; if the Ground be not naturally good so deep, it must be made good, least after the Trees have been planted some Years, when

they

they come to strike Root deep, they pierce down to a Poor, Cold, Barren Earth, and are thereby exceedingly hindred in their Progress; If the Ground be naturally good, then only dig and trench it well, without

adding any compost to better it.

Thus far it's supposed, that the form of this Espallier is agreed upon, as also the extent and largeness, and the Borders ready made, so that all is ready for Planting such Trees as shall be judged most requisite for this Work.

The several sorts of Trees that are mentioned before.

We will begin with the Elm, of which there are three forts, viz. The Dutch, the Witch, and the English, and are all fit for this purpose; but the Dutch and the Witch, are the greatest Growers, shoot freest, and come soonest to Persection.

If it's design'd to make an Espallier to be serviceable the first or second Year, then it will be requisite in the first place to make a Frame of Wood, or Rail, to which the Trees must be fasten'd after they are planted, because they must be of a much larger size than

those that are to grow up leisurely.

The Elms for this Espallier, to be serviceable the first Year, must be of two Sizes, the largest should be about eight or ten Foot high, the lesser about four or sive Foot high, to be good Brushy Trees from Top to bottom, as near as may be; let them be Prun'd, but so that the side Boughs may remain, to be spread out and fasten'd by Withs to the Frame.

These Trees must be Planted in the Border in a streight line, the largest size to be at three Foot distance from each other, and between all the largest size throughour, plant one of the lesser size, by which means there will be Planted an equal number of both sizes.

Avoid

Avoid Planting them too deep, it the Ground be Moist indeed you can hardly err in Planting of them shallow.

Let the Frame be made strong and substantial, and of a fufficient Heighth, the Posts fixed strongly to the Ground; when the Trees are planted, and fasten'd to this Frame, they will grow more uniform and upright, and thick from top to bottom. They must be kept fheer'd and water'd on all Occasions.

But Espalliers are to be made without a Frame of Wood to support it, and the Trees at first Planting, to be of a much smaller size, the largest may be five or fix Foot High, the leffer of four Foot, Plant the largest at three Foot asunder, and the lesser size between them as before, let them be Young thriving Trees, and the fuller of Boughs the better, but then the Boughs must be cut off within an Inch, two or three of the Stem, and as they Grow to be often sheer'd or clipt; that they may grow upright and appear uniform like a Wall, the Borders must be kept clean from Weeds, and carefully dugg every Year, but not so deep as to injure the Roots.

The Lyme or Linden Tiee, (call it as you Lyme for please) it fit for this use, chuse two fizes, Espaliers. let them be brushy thriving Trees, the largest fize may be fix or seven Foot high, the lesser three Foot high, to be planted in the same Order and distance as the Elms before mention'd, also to be Prun'd and Sheer'd like them, and the border flightly

dugg yearly.

Hornbeam and Beach, are inferior to Hornbeam and none for an Espallier, of those forts of Beach for Trees that shed their Leaves, and for E/paliers. some Reasons, may be preferr'd, as thus, The Trees grow naturally very thick, and hold their Leaves On the longest of any that shed them, the only Objection against them is, they cannot be planted to large as Elms or Lymes; but if the Planes be

rais'd from Seed, and have been transplanted, they come freely away, and if carefully Planted and Water'd, when necessary, they will prosper well, especially when they arive to be five or fix Foot high, they will shoot away strongly every Year: Chuse two fizes, the largest of four or five Foot, the small of two or three Foot, plant the largest at eighteen Inches asunder, the small between them, as before.

Maple, if planted of young Sees will make a good Hedge, and thickens well after Clip- Maple.

ping.

Alder, for a wet or moist Ground, makes Alder.

a very good Hedge.

White thorn and Privet, most People white-Thorn know will make very good Hedges, and Privet. but then they will not admit of being

planted so large as other Trees; but being planted small Plants, and as they grow up to be yearly clipt on the sides, they'l grow well without any Espalier Frame to support them. But these and all those plants that are planted small are not for present service, but must have some Years time before they can be of any Use.

We come now to speak of the Spruce-Fir for this Use, and indeed for such Persons as can secure their oranges and

other tender Greens for some sew Years, till an Espallier hereof be grown up fit to receive them is will be incomparable, and make a very beautiful and noble one; if the Planes are Young they will thrive very well, and may be clipt with Sheers every Year as they grow up; besides, by its beautifulness in appearing Green all the Year, it has a great Advantage over any of the former.

The benefit and advantage of this fort of Fir is more than any of the rest, by reason that it will endure cutting or clipping, better than the other sorts of

Fir, and after clipping it thickens very well, and is for this use the best sort of Ever-greens, for these two Reasons.

First, It's a very speedy grower.

Secondly. It endures clipping well, and thickens for

well after clipping.

The best way to make this Fir Espaiser is thus, make the Borders as before mention'd of good Earth, the young Firs to be healthy, thriving Plants, of two Sizes, let the largest be three Foot and a half or four Foot, the smallest of two Foot; the largest size should be planted about eight Foot asunder, with the smaller size planted between them as before, they must be taken great care of for the three first Years, to water them and keep them clean from Weeds, but in clipping of them, observe, not to clip them just against Winter, for thereby it causes the Tree to look rusty in the depth of Winter, but if they are clipt a little after Mid-Summer, they appear of a lovely beautiful Green.

Pine and Scotch Fir for Espaliers. The Pine and Scotch Fir, both these are much of a nature as to their growth, but are not so requisite for Espatiers as the Spruce Fir, because they will not endure

clipping so well, nor make so regular a growth, as we find by trial of some of them in our own Plantations at Brompton Park. As for the size and distance of Planting, use the same Method as for the Spruce Fir.

Laurel also is not unfit for this purpose,

Laurel for if carefully planted, and the Scituation not too much exposed to the Winds; the young Plans may be of two fizes, the

largest about three or four foot high, to be planted at three Foot distance, and the smallest about a Foot and a half, to be planted between the largest. It's a quick Grower.

The

The Holly is a most excellent Tree for making Espaliers continues green all the Winter, will grow exceeding thick, values not the Power of the severest Storms,

and may be brought into what thickness or form the

Projecter pleases.

The chiefest Objection against it is, that it's a slow grower, but that's only for the first, second, or third Years after 'tis planted, 'till it has taken strong Root in the Ground; but if Time and Patience be allow'd 'cill it be of sufficient Height, it will make abundant Recompence. Great care must be taken to get young thriving Plants of two fizes, the largest of one Foot and a half high, and planted about two Foot afunder, the lesser size of nine Inches or a Foot high to be planted between the large fize as before; if the young Plants be good and carefully tended, water'd and clipt, and the Borders flightly dug every Year, they will thoot away very fast, especially after they arrive to be four or five foot high, as for example, in the Hedges of our Plantation at Brompton Park, they have advanced two Foot, and two Foot and a halfin one Year.

As for Yews to make Espaliers, when they are carefully planted and well ordered, and time and patience allow'd fill an Espalier hereof comes to perfecti

Yew for E/paliers.

on, it makes a noble, firm and durable one, and for this use will excel the best Brick Wall, the young Plants may be of the same size as those of the Holly before mention'd, and manner of planting the same; they must be clipt every Year, and water'd on occasions, and kept clean from Weeds.

Apples and Pears come now to be spoken to, and some of them are fit enough for this purpose, the sizes which they ought to be of may be thus, the largest size to

Apples and Pears for Espaliers.

be Tall Standards, the smaller size to be Dwarfs, or

good bushy young Trees; the tall ones may be planted about four or five Foot asunder; these with care and good management will grow without a Frame of Wood, but in this, as in all others, it must be granted, that they are better with a Frame of Wood than without. If a Frame be made, let the side Boughs be fast ned to the Rail; let the small Dwarf Trees be planted between them as before.

It will be necessary in making of this Espalier of Apples and Pears to chuse such forts of them as do naturally aspire and grow upright, for there are some of both forts that are inclined to grow otherwise, Amongst

the Apples the Golden Pepin may be chosen.

This Espalier may have one advantage over the former forts, which is by its producing of Fruit every Year, and is likewise very useful for the bounding our Kirchen Gardens from the sight of Walks or Gardens of Pleasure. As for the proper forts of this use, it's best to consult with some ingenious Nursery Man, who will make choice of such as shall be fit for this purpose.

If an Espalier be made of Apples and Pears without a Frame of Wood, the Trees must be smaller, and of

fuch fize as is directed for the Elm.

Perhaps it may be thought necessary to add a Word or two as to what Aspect the entrance into this Espalier ought to be; hut herein every one may do as he shall think most proper, with reference to the place where it stands.

But some will object.

Is not a Brick Wall sooner made, more substantial, durable, and more effectual for this use than any of the former.

In answer to which, The principal design of these Espatiers is to deaden the violence of Winds, that the tender Greens and Plants which are encompassed by them may be serene and quiet; and Experience tells us, that the best Brick of Stone Wall, will not es-

fect

fect this, for Walls being compact and close built, have a strong Power to repulse and beat back the Force of violent Winds, to the great detriment of whatfoever is tender that grows near them, being sometimes rent in Pieces. But the most tempestuous Winds beating against these Espaliers; especially if made of Spruce-Fir, Holly, or Yew, they gently give way to its Force, without any manner of repulse, and hereby all tender Greens and Plants encompassed

by them are fafe and fecure.

But those that design to make an Espalier of any of the five forts of Greens before mention'd, and cannot flay till they are grown up, but want a present fecurity for their tender Greens; herein the best way will be, as we have tryed and found by Experience) to proceed thus. First lay out the Dimenfions for the faid Espalier of Ever Greens, make the Borders as before directed to those Dimensions, which plant at the proper Season with Spruce-Firs, or other foremention'd hardy Greens, to the outbounds of which all round, draw Parallel Lines to the several sides, 18 Foot distant from it, and here make another Border all round, and make a Frame of Wood as is before directed: After which Plant this Border with large Elms or Lymes, or any of the beforemention'd Trees that thed their Leaves The fize and manner of Planting them is mention'd before more at large; tho' for this use, the larger the Trees, and the higer the Frame, better.

These large Trees will form themselves thick with their Leaves, the first and second Year, and afterwards will to continue, and are of great use till the Espalier of Ever-greens is grown up of a sufficient Heigth, to be a security of it self, after which the said Elms or Lymes may be taken up, and Planted elsewhere, in some place not far off, either to make a View, or

some other proper place of Shade near to Houses: And

And now as to what has here been humbly offer'd, it may possibly be thought to proceed from some referve of self interest, to those of our Profession.

To this we answer.

That fince the fuccess of our Industry hitherto hath Establishe us a Reputation, amongst so many Nobleand Worthy Persons as have been pleased to make use of our Service, we have no cause at all to apprehend the loss of the continuance of their favour and good Opinions, or any need to feek it by mean and deceitful ways.

Those who will but consider with what Freedom and Plainness we have endeavour'd to lay down the Directions we here Recommend, will foon, and in Justice too, absolve us of any unworthy design, or other than what is for the Publick Good; fince there could not be indeed a readier way to ruin our Reputation, than thro' our filence to suffer Gentlemen, the noble Patrons and Encouragers of our Labourers (and who have been at fo great Charge and Pains to Cultivate and Adorn their Gardens) to want the best Dire-&ions we can give; or a better to preserve our Credit with them, than by discovering to all the World what (not by Conjecture only, but by long Experience, and our own many Years diligent Observation.) we find the best Expedients to keep and maintain them in their Beauty.

It really grieves us more to see a Garden of Curious Plants miscarry, thro' any of those destructive Accidents we have mention'd, than any advantage which may be thought to Accrue to us, by the supplies that are daily fetch'd from our Magazines and Nurseries; to repair and furnish what is lost, can be the least fatisfaction to us: It being our best and only true interest, that all we do should prosper; from such incouragement it is we are fure to Thrive with the

Favour

Defence of Gardens. xxxv

Favour and Good Will of those who are pleased to employ us, and make good use of these Directions with a Blessing from above. If Planting be undertaken in Youth, with what pleasure may a Person view the successive growths of his Industry, and in his own time behold his new Plantation in much Maturity, and then not only will a Ressection be grateful, but this

Accommodation delightful.

To Conclude, All we have here said relating to Espalliers, and of their great use and Benefit, we again Recommend to such as would enjoy the most Noble and Instructive Ornament of a Garden in variety of Greens, and preserve them in a flourishing Condition. How contrary it is to our Inclination that any should Miscarry, we hope we have ingenuously declared, in our giving the plainest Direction for their Preservation, grounded on long Experience, which we as freely Communicate, as we shall farther do, if this meets with Reception and Encouragement.

FRUIT-GARDENS,

AND

Kitchen-Gardens.

CHAP. I, and II.

That a Gard'ner ought to be well skill'd in the Culture of Fruit and Kitchen-Gardens.

S Gardens seem to be in a perpetual motion. always acting either for good or ill, according to the good or ill Conduct of their Master: so they seldom fail, either to recompense the Diligent and Ingenious, or severely to punish the Lazy and Unskilful. There is daily some new thing to be done, as to Sow, Plant, Prune, Pallisade; to fee Plants grow, Legumes Imbelish, Trees Blosfom, Fruit Knitting, then Thickning, Colouring, Ripening, and at last to gather them; and yet this to necessary a Skill is not so extremely difficult, as 'tis generally thought to be. For having had the Honour of being near Thirty two Years Director of all the Fruit and Kitchen-Gardens of the Royal Family, I do affirm, for the satisfaction of the Ingenious. that 'cis very easie to attain to as much Knowledge

as is reasonably necessary for the Curious, either to avoid what might perplex them, or at least put them in a Condition of enjoying their wishes; provided due attention be given to the following Rules.

The First relates to the Quality of the Ground, its necessary depths, Tillage, and Amendments, and the

ordinary Modeling of useful Gardens.

The Second concerns the Choice of Trees well qualified, either in or out of the Nurferies; the Names of the principal Kinds of Fruits of every Season, to be able to distinguish them, and what number of each the compass of his Garden may require. To know how to prepare the Heads and Roots of Trees before they be put into the ground again, to place them at a convenient distance, and in a good exposure, and then to know (if not all) yet at least the Principal Rules of Pruning, either as to Dwarfs, or Wall Trees. How to pinch off some Branches that are over vigorous, to Pallisade such as require it, to trim such usels Budds and Sprigs as cause confusion; and lastly, to give every one the Beauty they are capable of.

The Third relates to the making of Fruit grow Large, and Beautiful; to gather them prudently, and

ear them feafonably.

The Fourth relates to Grafts on all forts of Fruit-Trees, whether in Gardens, or Nurseries, both as to

time, and manner of applying them.

The Fifth relates to the general Conduct of Kitchen Gardens, especially to understand the pleasure and profit they may yield, in every Month of the Year.

These Articles not being many, the Curious may in a little time be fully instructed by the following Abridgment.

C H A P. III.

An Abridgment of the Maxims of Gard'ning:

First ARTICLE.

The Qualification of the Earth or Soil.

THE Soil of a Garden is known to be good for Fruit Trees.

1. When all which the ground produceth of it felf, or by Tillage, is Beautiful, Vigorous, and Abundant; nothing poor or small, which should be strong; or yellow, which should be green:

2. When in ismelling to a handful of Earth, it

gives no ill fcent.

3: When 'tis easie to Till, not over strong, or stiff.

4. When you handle it, 'tis mellow, without being too dry and light like Turf Earth, or like ground

altogether Sandy.

5. When 'tis not over-moift, like Marshy ground, or too hard, like Loomy ground, which is often at the bottom of good Meadows, coming near to the nature of stiff Clay.

6. Lastly, as to the Colour, it must be chiefly of a blackish gray, and yet there's some redish that does very well; I never saw any both very white and good.

Second ARTICLE.

Of the Depth of the Ground.

IF the top appears good, you must have three foot deep of the same Earth, which is very material,

and of which you ought to be pretty well assured, by sounding the ground in five or six places; 'tis a great Error to be satisfied with less depth for Trees.

Third ARTICLE.

Of Tillages.

Tillage the oftner made, the better for Trees;

there must be at least four yearly, viz.

At the Spring, digging or stirring with Forks;
At Midsummer by cleansing and stirring the surface
of the ground.

At the end of August, the same as at Midsummer, and just before Winter, by well digging, and clean-

fing the ground from Weeds.

Besides these stirrings, or diggings, its suppos'd that the ground be clear'd from Weeds, as often as need requires. It must never be unmanur'd, nor trampled, nor beaten.

Small Plants, as Strawberries, Lettice, Succo-

ry, &c. must be often Weeded.

Fourth ARTICLE.

Directions for Amendments.

A LL forts of Rotten Dung are excellent for groundsus'd for Kitchen-Garden-Plants, Sheeps Dung when rotten, is good for most forts of tender Plants.

But it and most sorts of Dung are of the greatest use to all Plantations of Fruit-Trees, and a general amendment, if thus apply'd, viz. That is, on second Borders, against Walls, in Dwarf Plantations, or in Nurseries, and such like, which requires amendment, the ground to be dugg, or locsened with Forks in August, September, or Ostober, accord-

ing as a moilt Seafon shall offer it felf; after which. lay on the feveral forts of Dung, Sand, Challe, Sea-Coal Ashes, &c. as shall be most proper for the nature of the Soil. These Dungs being thus laid on, and spread abroad, the Winter Rains and Frosts will wash it into the ground, to nourish most part of the Roots, and render the Earth healthy; and all Trees or Plants growing thereon, will receive the full benefit thereof. And we are most certain that by this fort of Improvement, one Load will do more good, than two Load us'd the common way of laying it on the ground and Digging and Trenching of it in a foot or more under ground. There is near London, a fort of Street-Soil, fo call'd, because it's the cleanfing of the Streets, wherein there is a great deal of Sea-Coal-Ashes; this fort of Soil is of very great use, with a little rotten Horse-Dung, or 'Neats Dung mixt, and laid on Land as aforefaid, especially for all stiff and wer Land, it makes great improvement, for it contains a great quantity of Salt in it, by which it much enricheth the Soil, and hollows all stiff and wet Land, whereby the Water 'passeth thro' the freer.

Fifth ARTICLE.

Fruit and Kitchen Gardens, is in well regulated Squares, to that if possible, the length may exceed the breadth. The breadth of the Walks must be proportioned to the length and extent of the Garden, the narrowest not less than fix or seven soot, the rest in Squares, not to exceed fisten or twenty Fathom, or thirty or forty yards on one side, to a little more or less on the other; they will be very well of ten or twelve Fathoms on one side, to source or fisteen on the other; common Paths for service, ought to

B 3

be about two Foor. No Kitchen-Garden can succeed without a Conveniency of watering.

Sixth ARTICLE.

Rees fit for Planting must have a clean shining Bark. Shoots long and vigorous; sound Roots, and proportionate to the Stem, not too hairy, streight, and of one Stem.

Seventh ARTICLE.

hairy Roots, if they be dry, or dead, if not, leave some; preserve a sew thick ones, but cheifly the youngest and best, which have a more redish and lively colour than the old ones, and must be Prun'd reasonably short, only the bruis'd ends cut off on the lower side, according to their thickness. In Dwarfs let the longest be not above eight or nine Inches, in high Standards about a foot. If Roots be not bruis'd in taking up, it's better to leave them longer; more may be allow'd to Mulberries and Cherry-Trees; weak Trees, according to their thickness, may have three or four Inches. 'If there be five or six Roots spreading equally about the soot, and well plac'd, tis enough.

Eighth ARTICLE.

IN order to plant well, you should chuse dry weather, to the end that the Earth, being dry, may easily fill up between the Roots.

The time to Plant Fruit-Trees, and all other Trees that lose their Leaves, which are equally hardy, is

from the end of September, to the beginning of March, and sometimes both sooner and later. 'In wet ground, the Spring is better than September, or October.

'Let not the end of the Root be above a foot in the ground, cover the upper part of the Root with about eight Inches of Mould, then apply half rotten Dung thereon, laying on that a small quantity of Earth, after which, apply Fern, Litter, or Straw thereon, which will keep the Roots warm in Winter, and moist in Summer. After the two Roots are Prun'd, cut the Stem to its designed length, before you Plant it.

The propertion of the heighth of the Body of the

Dwarf may be from 8 to 18 Inches.

High Standards about 6 or 7 foot, in all Soils; let none of the Roots incline straight downwards, but, if possible, spreading on each side.

Trampling or treading spoils small Trees, but is necessary to great ones, to secure them against the

Winds.

Set not too deep irrany ground, especially in wet ground, the shallower the better, and raise little Hills

above the Roots, as before directed.

Wall-Trees must be distanced by the goodness of the Earth, and height of the Wall. If the Walls are 12 foot high, let one Tree shoot up to garnish the top, between two to garnish the bottom, planting them within 5 or 6 foot of each other. But for Walls of 6 or 7 foot high, the Trees may be Planted at about 9 foot distance.

Ninth ARTICLE.

THIS relating all to Pruning, is referr'd to the Fourth Part, which Treats largely on that Subject.

B4: Tenth

Tenth ARTICLE.

S to Espalliers or Wall-Fruits, the Branches ought to be Pallisado'd or spread about May, by an orderly disposing of the Branches to the right and left, which incline to each side to avoid consustion, as also in respect of Barrenness, and to avoid crossing one another. But Barrenness being the greatest desect, Crossing must not be scrupled, when Barrenness cannot otherwise be avoided.

Preserve all the fine Branches which Peach-Trees shoot out, unless they prove so numerous as to cause consussion. However, if necessity require, cut close some of the most unruly Branches; likewise take away the Branches of salse Wood, which sometimes grow in the front of Pear Wall Trees, as well as those growing in the middle of Dwarfs, which is call'd the Trimming of Budds, or useless Branches.

Eleventh ARTICLE.

HIS relates to the gathering, laying up, and ordering in the Store-house, such Fruit as do not ripen upon the Tree; for which I referr you to the Treatises upon this Subject, which are the 7th, 8th, and 9th Chapters of the 5th Book.

Twelfth ARTICLE.

HIS Article being only of Grafts, and Nurseries, the Reader is referr'd to the 11th Chapter of the 5th Book, where the Author Discourses at large on these Subjects.

Thirteenth

Thirteenth ARTICLE.

THIS relates to Kitchen Gardens, and the works of every Season, which is also referr'd to the 1st, 2d, and 3d Chapters of the 6th Part where the Reader will find several useful Calendars, and Alphabets of works to be done, relating to the Provisions for, and Products of every Month in the Year.

CHAP. IV.

F this the Author makes no other use, than to write a tedious enumeration of the several Qualifications requisite to a good Gard'ner; all which may be summ'd up into the following short Character. Viz.

He should be neither too Old, nor too Young, Vigorous and Active, of good Capacity and Experience, of known Diligence and Honesty, of good Nature and Affability; and no doubt but these Qualifications will recommend him to any Person of Quality.

The End of the Abstract of the First Part.

OF

FRUIT-GARDENS,

AND

Kitchen-Gardens.

VOL. I. PART. II.

Shall here Treat of Four Things.

1. Of the Conditions necessary to a good Fruit and Kitchen-Garden.

2. Of Earth in General.

3. How to Correct the Defects in Gardens ready made.

4. Of Cultivating Gardens, with an account of the Soil proper for each fort of Fruit.

CHAP. I.

Of the Conditions necessary to a good Garden.

- HE Ground must be good, whatever the Colour be.
 - 2. The Situation must be favourable.
- 3. A good Convenience for Water.
 - 4. The Ground to be upon a small Rising.

Vol. I. The Complete Gard'ner.

5. Of an agreeable Figure, and good entrance.

.6. Enclos'd with reasonable high Walls.

7. The access to be easie and convenient.

Let us now try whether these Articles, and the execution of them, be grounded upon sufficient Reafon.

CHAP. II. Of Earth in General.

Contract our Author's many distinctions of Sands and Earth, we shall reduce them to Five General Heads.

Those that are moderately fat, unctuous, and stick-

ing together, make strong Earth.

Others more inclining to it are Loomy Earth, such as are extreme unctous make Clayey and heavy Earth, unfit for Culture.

Of these some are black, red, white, and grey, but Colour is not very essential to the goodness of

Soil, as we shall prove hereafter.

The fourth is of the several sorts of light and Sandy, which are of a hollow nature, and very proper towards the meliorating and manuring the heavy Earth before mention'd.

The First is of a Sandy, Limy nature, in which generally speaking most Trees thrive best; and if it has a small mixture of Stones in it, we find no injury in that, but rather a benefit to the Roots of the Trees therein Planted.

The large Cherry-Trees of the Vale of Mount Morancy, and the fine Plumb-Trees of the Hills of Moudon, inform what Soil is proper for Cherries, and what for Plumbs. Sometimes in a small compass of ground there are veins of Earth extremely different; for Wheat grows well in many places, though

close by perhaps the ground is fit only for Rye, and so likewise for Grapes, and other Fruits. And many things succeed well in England, which will not thrive in France: And so on the Contrary.

CHAP. III.

Of the necessary Conditions requisite to a good Earth.

2. It must casely recover it felf, when worn out.

3. It must have no ill taste, or scent in it.

4. It must be at least 3 foot in depth-

5. Free from great stones, and easie to Till.

6. Neither too moist nor too dry.

Which Maxims I explain in the following Sections

Viz.

First, The First proof of a good Earth is, when of it felf it produceth Trees having vigorous and numerous Branches, where the Plants grow with large thick

Leaves, and the Trees grow up in tew years.

Secondly. The second proof of good Earth is, that it easily repairs what injuries it shall receive by great Droughts, great Moisture, or long Nourishment of Foreign Plants, tho' much depends upon the situation. Therefore take it as a Maxim, that no Earth can be said to be good, which shews not its Ferrility by its Productions, and is likewise able to recover it self when brought low. These are the Earths for Fruit-Gardens. As for Kitchen-Gardens, I do grant, that having a full supply of Dung, and Water, the Industrious Gard'ner may do Miracles.

Thirdly. The goodness of the Earth does also confust in having neither smell, nor taste; since all our Fruits and Legimes will infallibly be tainted with

whatever

whatever is ill or unsavoury in that kind; a convincing proof of which, are those Wines that taste of the Soil.

The taste and smell may be tried by smelling to a handful of it, or soaking it in Water, and straining it thro' a Linen Cloth.

Legumes require not so much nicety, because the boyling throws off what might be unpleasing to the taste.

Fourthly, A farther enquiry into good Earth, is to found the depth of the ground, to try if it be at least 3 foot of as good Mold at the top is; and if (with long use) this Earth become almost worn out, you may recover it, by throwing what lay at the bottom up to the top.

Without this choice of sufficient depth of Earth, your Trees and Legumes will grow yellow and sick, many of them perish, and after five or six years patience, when you expect the benefit, you'l be oblig'd

to be at the expence of a new Plantation.

Fifthy, A good Earth, without being too light, ought to be easie to Cultivate, pretty tree from great Stones;

if there's but a few, they do little or no harm.

Light Moulds do very much multiply the Roots of Plants, by drinking in the Rains, and Watering, and makes easie passage for the Roots to run in; they are also easily impregnated and kept warm by the Sun,

and consequently quick in production

Earth which is too strong and cuts like Loomy or stiff ground, is apt to close and grow hard, to such a degree, that Rains or Watering will scarce soak into them; such Earth is naturally inclined to rottenness, is cold and backwards in productions, keeps a continual moisture at bottom, apt to split and crack in great heats, insomuch that they are incapable of Culture, prejudicial to Trees and Plants that have newly taken Root, by uncovering some, and breaking others.

but

But all such Grounds as are so stiff, are pernicious to Trees, without care be taken, which in all Planting ought to be very high (nay rather) on the top of the Ground, than in it, raising a sufficient quantity of good Earth to the Roots of each Tree, so that when the Roots of the Trees shoot, they have the benefit of the best Earth that lies on the top of the Ground, and are not confin'd in the wet Earth which the nature of the ground produces, as they would be when planted low in all those sorts of Grounds. But there is an excellent Method for Manuring and Meliorating of such Grounds, by digging it up in the Winter, and laying on a Coat of a certain fort of Dung call'd Street-Soil; as is explain'd more at large in 5th Page of the First Part.

We come now to the Cure of the defects of an

Earth too light and dry.

The First Expedient is to remove as much of that Sandy Earth as will amount to 3 foot deep, and afterwards fill that up with as good Earth as you can get, of a stiffer nature, with a good mixture of Cow-

Dung.

'As for the removing of such dry Earth as the Author describes, undoubtedly the Directions may be good for a Prince's Pocket; but this being design'd for the publick good, and for the use of all honest Country Gentlemen, it may be accomplish'd without that Charge; viz. In bringing in a certain quantity of more solid Earth mixt with Cowdung, to mix with the other Earth, which will conduce much to the improvement of it.

The Second is to keep the Cultivated Places formewhat lower than the Walks, that the Water which

falls upon them, may run into that Ground.

Or, Thirdly, throw into those Cultivated Places all the Snow which shall happen to lie upon the Walks, and other parts near at hand, during the Winter.

Thefe

These Experiments we have persuaded our Friends

to practife, with great success.

Sometimes there lies water about three foot underground, as it commonly happens at the bottoms of Vales, or where there lies a good black Sand; this water is naturally raif'd to the top, always keeping the Earth in good temper for production. Whereas on the contrary, water lying within a foot, or fomewhat more, being there stopt by Chalk, Stone, or stiff Clay; if some way be not sound to discharge this water, the Soil will grow cold, rotten, and stark nought.

In Cold Countries light Earth is to be preferr'd, because 'tis made warm by a small Heat; but on the contrary in Hot Countries, a strong sat Soil is best, the heat not so easily penetrating, or drying up the Plants

Therefore happy are they who pitch upon a fertile Soil, without talte, sufficiently deep, moderately light, pretty free from stones, neither too strong and moist, nor too light and dry.

CHAP. IV.

Of other Terms us'd in discoursing of Earth.

Of worn-out Earth.

He most Fruitsel Earth will in time be worn out by the multitude of its productions; I mean such as are forced upon it: but where it bears what is only natural and voluntary, as the ground of a good Meadow, it suffers no detriment; but when you go about to force it to produce Saint-Poin, Wheat, or any Grain that is a stranger to it, you'l soon find it to slacken and abate of its Crop, and in the end grow poor, and want help to put it into heart again.

16 The Complete Gardner. Vol. 1.

All Earth according to the different quantities and kinds of Salt wherewith it abounds, shoots forth several different kinds of Plants, sometimes altogether and at the tame time: witness the ground of good Meadows. The like may be faid of Grounds long us'd for Vineyards, Woods, Forests, Orchards, &c. which when destroy'd, we cannot expect that they should succeed again with the same Plant, because its too much wasted. But it may do well for smaller Plants, as Pot-Herbs, Pease, Beans, &c. In this the Gard'ner must shew his skill, in knowing what Plants should succeed each other. But if he should be oblig'd to Plant new Trees, in the room of others that are dead, then there is some work to be done; of which hereafter. The manner of imploying Earth you will find more at large in the Treatife of Kitchen-Gardens.

Of Fallow-Earth.

Fallow, or Earth that lies at rest, is such as is lest unemploy'd, in order to recover and re-establish its former truitfulness; whether by the Influence of the Stars, or Rains, I determine not; but 'tis plain that good Earth having been much impair'd, if laid Fallow, and a little Dung laid thereon, or Straw burnt upon ir, will easily recover its natural Fertility.

Of Transported Earth!

This Expedient of Transporting Earth is seldom us'd, unless when a Garden is to be made in a place where there is none that is good, such Earth does really improve by thus removing of it, and is evident; which proceeds either from the Air, or else by making of it lcoser, and more penetrable to the Roots.

Of New Earth.

New Earth is such as never serv'd to the Nourishment of any Plane viz fuch as lies Three Foot deep, or as for as seed, as go, if it be really Earth; or elle Earth that has been a long me chuile open, the' formerly is that over home, both a new first are extreamely good bob for Command Pers. Or akowito Earth ont it from Rich is there to count of a pandy Loamy Nation, who are a referred in an heart a tital fact, is of excel and the most fores of plants, a pechely in it has been in own up in heaps to meliorate, and have 5 taken the Winter Frotts, it will be so much the better.

of the Colour of Good Earth.

There is good and bad of almost all Colours, but 'is the blackish gray that pleaseth most, and has had the approbation of former Ages. I have often met with reddish and whith Earths that have been incomparable, but feldom any quite white that deferv'd that Character. There is some that is black on the top of Hills, and also in Vales, which is only a dead Earth; the most certain Argument of it's goodness, is the Strength, Vigour, Brauty, and largeness of the Plants and Herbs that it produceth,

CHAP. V.

Of the Situation of Gardens.

S to a Kitchen-Garden, little Vallies or low A Grounds are to be preferred to all other Situations, and have commonly all the advantages that can well be desir'd, the Mold easte and of tufficient depth, 'tis fatten'd by the Neighbouring Hills: Le. gumes grow here: Easie and plenty Waterings are at hand. But then they are liable to Inundations; by which Afparagus, Artichoaks, Strawberries, &c. are utterly destroy'd, when they come to be long overflow'd.

As for Fruit Gardens, certainly Ground Moderately dry, and indifferent high are the best, provided

it be good in it felf, and deep enough.

If Choice Fruits grow not so large on such Grounds. yet it is recompensed in the beauty of the Colours goodness of Tast, and Forwardness. How delicious are the Winter Thorns, Bergamots, Lansac, Petit-Oins, Louis Bonnes, &c. growing upon an elevated Ground, compar'd to those in a Meadow-ground, which shews the importance of the Situation of Fruit-Gardens. But for Fruits and Legumes, nothing is beter than a rising Ground, if good in it self, the Waters above constantly washing, but not staying upon it, affords it a proper temper, the Sun performing its part, and freeing it from the danger of cold, which Marshy Grounds are always subject to.

CHAP. VI

Of the Exposure of Gardens, and what may be good or ill in either of them.

Here are Four forts of Expositions, East, Wells South, and North. Thele Terms among Gardners, fignifie the contrary to what they do with Geo. graphers: For the Gard'ner only intends those Parts or Walls of the Garden upon which the Sun directly shines, and in what manner it shines the whole Day; either as to the whole, or as to some sides of it. for instance,

If the Sun at his Rifing, and all the first half of the Day, continues to shine upon one side, that is the Rast side; that upon which the Sun shines the latter half part of the Day is the West; that part where it shines longest in the whole Day is the South; and that side on which it shines least, is the North. 'Tis true, that whatever Situation a Garden is in, it must have all the Aspects of the Sun, except such as lie against Hills, or the sides of Mountains; some have the rising, others the setting Sun: But for such as are situated upon open Plains, the difference of the Exposure is not so sensible.

If your Garden be of strong Earth, and consequent-

ly Cold, the South Exposure is best.

If it be Light, and Hot, then the East is to be preferr'd: A Southern Exposition is often subject to great Winds, from the middle of August, to the middle of October; for which the Stalk; as the Virgoules, Vert Longues, St. Germines, &c. suffer much; others do better resist the Winds, as the Thorny-Pears, Ambretts, La Chasseries, Dry-Martins, &c.

"Note. That where the Author speaks of the Virgoules, Vere-Longues, St. Germines, &c. Planted Standards, it's to be understood in reference to France; for here in England they require a good South Wall; for if they are planted either Standards or Dwarfs, it's very rare that they such

" ceed.

The Eastern Exposure is subject to North East Winds, which withers the Leaves and new Shoots, especially of Peach-Trees, blowing down much Kernel, and Stone-fruit; moreover the Eastern Wall-trees have little benefit of the Rains, which seldom come but from the West.

The Western Exposure dreads the North West. Winds in the Spring, and the Autumn Winds, those

throwers down of Fruits.

66As

"As for the Northern Aspect here in England, we "find it most proper for Baking Fruits, especially

" Pears; also some sorts of Plumbs, and Morella Cherines may be planted there, to succeed the Cherries

of planted in other Exposures.

In short, all Expositions have their perfections, and imperfections; we must take our best advantage of the first, and use our best skill to defend our selves against the last.

CHAP. VII,

Of the Conveniencies of Waterings for Gardens.

HE Spring and Summer are subject to great Heats, and Scorchings; for which reason, the Legumes or Plants of that Season, acquire the largeness, thickness, sweetness, and delicacy which they ought to have; but will be always bitter, hard, and insipid, unless helpt by long Rains, which are very uncertain; or else plentiful Waterings, which we ought to have at command: And therefore the small Plants, as Strawberries, Greens, Pease, Beans, Sallads. Sc. may be supplied by Rain, yet Artichouks of a year or two's growth must have a Pitcher two or three times a week ro every Root, else Gnats will annoy them; the Heads will be small, hard, and dry, and the Suckers will only produce leaves.

During Seven or Eight Months, there is generally a necessity of watering all that grow in Kitchen-Gardens, except Asparagus. But April and May being the two Months for blasting, and drought, there is often a necessity of watering every new planted Tree, nay sometimes those that have store of green Fruit, especially if the Earth be dry and light, may be watered till August, less the Fruit prove small,

stony, and not palatable.

The

The most common, but worst of Waterings is that of Wells; 'tis true, they are necessary, where no better can be had; but Rain-water, or Rivers, or a Canal, or Pond well stored with Pipes, to distribute water into the several parts of a Garden, are the Soul of Vegetation,

CHAP. VIII, and IX,

That the Garden ought to be partly upon a Level, Of a Pleasant Figure, and well plac'd Entrance.

Reat inequlities are troublesome to Gardene, the overslowings of Rains causing great disorders, and much trouble to repair them; small unevenants do no great harm, rather good in a dry Earth; and yet in Gardens too much inclining to drought, or that he high, and of a perfect Level, twill be proper to allow them a little inequality, such a one as may be unperceiveable, and yet continue in all the Soutnern Walks, that the Water that in them is of no use, may fall to replenish the Roots of the Trees, &c.

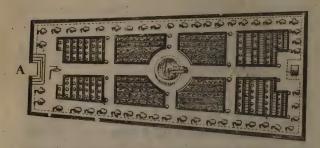

The best Figure for a Fruit or Kitchen Garden, and most convenient for Culture, is a beautiful Equare of straight Angles, being once and a half, if not twice so long as 'tis broad, viz. From Forty yards, to Twenty, or Twenty Four; from Eighty yards, to Thirty Six, or Forty; from one Hundred and Sixty yards, to Eighty, one Hundred, or one Hundred and Twenty; for from Squares it's most easie to raise uniform Beds of Strawberries, Artechoaks, Asparagus, Sc. or of Chervil, Parsy, Sc. which cannot well be done in an irregular Figure.

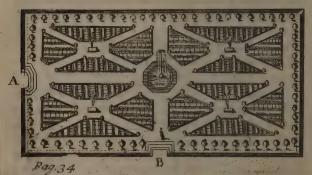

If the Kitchen Garden be large, the Entrance should be just in the middle of that part which has

3 the the

22 The Complete Gard'ner. Vol. I.

the most extent, as appears by the Figure at the point A, in order to face an Alley, which being of the whole length of the Garden, will appear stately, by dividing of thewhole length of the Ground into two equal parts, each of these composing Squares or Plots too long in proportion to their breadth, must be subdivided into smaller parts.

The Entrance would not appear so well in one of the broad sides, as Letter B.

When under a necessity, I have made fine Gardens, which have had their Entrance at one of the Corners; such is the Kitchen Garden at Rambouillet, and yet no body finds fault, because the Entrance faces a fine Alley, bordered all along with Espaliers, or Walls full of Fruit.

And

And tho' this Figure be not the most perfect, yet I have made a fine Kitchen-Garden of 220 yards in length, and 120 broad, resembling the Figure of a Lozenge; and tho' the Entrance has been made in the middle of the narrowest side A, yet'tis not easie to dinguish so small an irregularity; for tho' the Angles are not equal, it nevertheless hinders the Plats from seeming perfect in their proportion.

CHAP. X, and XI.

A Garden must be well inclosed with Walls, and not far distant from the House.

Wall well garnished, Dwarfs well ordered, and vigorous; all sorts of good Fruits of every Seaton, fine Beds and Plats surnished with all sorts of Legumes, clean Walks of proportionable largeness, neat Borders well fill'd with useful things, a well-contriv'd variety of what is necessary in a Kitchen Garden for all Seasons) these are the things that we ought to have in our Gardens, and setting aside all manner of Prospects, a Garden ought to be inclosed with Walls; for belides the shelter they afford against trouble some Winds, and Spring Frosts, it is impossible to have early Legumes, and fine Fruits without the help of them; besides many things that would scarce be able to grow in the hottest part of Summer, are affected by the favour of a Wall.

In short, Walls are so necessary, that to multiply them, I make as many little Gardens near the great one as I can, whereby I have more Wall-Fruit, and better shelter.

Those Persons who have several Gardens, 'tis necessary that those for Flowers and Sbrubs, we mean the Parter's should face the principal aspect of the House for nothing can be more Charming, than to see at all,

C4 .

times on that side an agreeable variety of a succession of Flowers; therefore without prejudicing the Parterre, we place our Garden in the best ground we can find near the House, of a convenient access.

Such as can have but one Garden, it will be far better to employ it in Fruits and Legumes, than in Box and Grassplats; in such a case, if the Ga-den be indifferent large, twill be convenient to take the nearest part of it for a Parterre leaving the rest for things of use and necessity.

If the place be not large, then make no Parterre, but resolve to employ it in Plants for use, placing the most pleasant part of the Kitchen Garden most in fight of the House. A fine well plac'd Arbor for shelter in case of a storm, or to veiw the Culture of the Ground, will not do amis.

CHAP. XII.

How to Correct defective Ground, either as to quality, or want of quantity.

THE defects of Earth may be reduced to Five Particulars.

1. Bad Earth.

2. Indifferent.

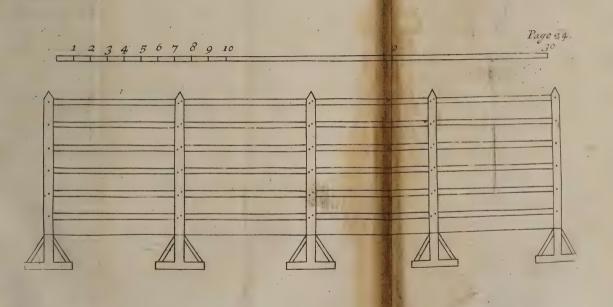

3. Indifferent good, but not enough of it.

4. To have no Earth at all.

5. The the Earth be never to good, yet the great moissure to which it may be subject, may make it in-

capable of improvement by Culture.

1. If the Earth be detective, for that it flinks, or is meer dead, watery Loom, or elfe flony, gravelly, or full of Publes, or only dry Sand. In this Cafe it must be taken away to the depth of Three foot in the principal places of the Garden, vizi for Trees, and long rooted Plants, and Two Foot for lesser Plants,

filling it up with the best Mould you can get; and if this be intended for the Garden next the House, it ought to lie Two or three Foot lower than the House, from whence there ought to be a Balluster, with some steps to come down into this Garden, which is a great Ornament.

'But as to what has been said heretosore, as relating to a Prince's Pocket, this may do very well, but the Charges being so great, it will be best to use the aforesaid Directions, in bringing in a certain quantity of Dung and Earth of a more agreeable temper, to

intermix therewith.

As to the Second Case, in which the Ground having a difficient depth, yet the Earth is nevertheless but indifferent, either too dry and light, or too tough and moist, or else too much worn out; in this case must be taken to mend it by mixing new Earth with it, with this caution, that you mix loomy Earth with what is too light, and landy mould, with that which is too tough, and that which is really wood, with that which is worn out, unless you intend it should recover it sell by rest.

"And as for improving of it by Dung, observe that all moist Dung, such as Cow-Dung, is proper to be mixt with light Earth, and Dung of a light nature to be mixt with heavy Clay, or Cold loomy

" Earth.

3. If it be really good, but not enough of it to make Three Foot deep, you must consider whether the top of the Earth be of sufficient heighth; if it be, then all that is naught must be removed, and good

added, to make up the depth requir'd.

If the waters are naturally in the Earth, they must cither be turn'd aside at a distance, by Gutters, or Drains; or else you must raise the whole Plats, or only the great Beds upon ridges, making deep Furrows to serve for Paths.

If

If these moistures are only occasion'd by great Rains, you must use the same Remedy, by raising the Earth, and making Gutters or Drains to carry it off.

CHAP. XIII.

THis Chapter treats of the Slopings, Railings and fallings in a Garden, and is judg'd to be of no

use, by reason of the infinite varieties which are to

be found in Grounds, and for which no certain Di-

rections can be laid down.

CHAP. XIV, XV, XVI, and XVII.

Of the Distribution of the Ground of a Fruit and Kitchen-Garden.

Good Kitchen Garden ought to be plentiful in its productions, agreeable to the Eye, and convenient for Walks and Culture. To which purpose, it should be employ'd with all the good order and prudence that may be, with Plants and Seeds suited to the several parts of it: It must be distributed into convenient Squares or Plats, with Walks very neat, well placed, and of suitable fize, which must never be narrower than five or fix Foot, be the Garden never so small; and ought not to exceed Eighteen or Twenty be the Kitchen Garden never fo large.

In a small Garden, the Entrance ought to be in the midst of that breadth, with only one Walk of about

Six Foot.

"The Author enlargeth farther, about the differ. "ence of Walks, which is judged needless; as also " what he adds farther in this Chapter, relating to " Espalliers, which is nothing advantageous to the

Reader, and not fit to be put in practice in Eng-

66 Espalliers are more frequent than Walls.

For a Garden of Twenty or Twenty Four yards, whether the Entrance be at the middle or on one fide; in both Cases the works ought to be seven Foot broad, nay Eight or Nine, in that which is parallel to the Front of the House.

CHAP. XVIII, and XIX

"THESE Chapters Treats of Gardens of various Sizes, from Thirty to Forty Yards; from "Fifty to Sixty, and so on, proceeding to Gardens "of an extraordinary size, but the Directions are "judg'd to be of very little or no use."

CHAP. XX, and XXI.

Of the manner of Cultivating Fruit-Gardens and of Tillage.

IF we would have our Trees particularly our Dwarfs and tall Standards, well fed, very vigorous, and agreeable to fight, we must take Care.

I. That they be not too near one another.

2. That no forts of *Plants* be near them, which may inwardly steal their nourishment, or outwardly hinder the refreshings and helps they are to receive by Rain, or Dew.

Take care to keep the Earth always light and clean, and therefore often Cultivated, that the Earth may be nourished both by the Rains, Sun, and Dews, To which end, we must be careful to till, amend, and cleanse the Ground, as often as it requires.

Whas

What Tillage is.

Tillage is a moving or stirring, which being perform'd on the top of the Ground, enters to a certain depth, and makes the lower and upper parts change

place.

Earth that is hot and dry, must be Till'd in Summer time, either a little before, or whilst it Rains, or soon after, or when there is likelyhood of more; at which time, you can neither Till too often, nor too deep; but (by the Rule of Contraries) they must seldom be Till'd in very hot weather, unless they be water'd immediately after.

Earth that is cold, strong, and moist, must never be Till'd in time of Rain, but rather during the greatest

Heats,

flures over.

But we find that there are several Grounds that will not work till after Rains; at which time it's the best time for Tilling, and bringing it into Order.

The frequent Tillings hinder part of the goodness of the Earth from being wasted by the growth and nou-rishment of ill Plants; but these Tillings are not wholly sufficient, unless care be taken to Hoe and pull up those ill Weeds which usually grow in Summer and Autumn, and multiply without end, if suffer'd to run to Seed. But (by the by) you must know, that in the times that Trees blossom, and Vines shoot, Tillage is very dangerous.

To dry Earths, I allow a large Culture or Tillage at the entrance of Winter, and the like as foon as 'tis past; that the Snows and Rains of the Winter and Spring may easily sink into the Earth. But to strong and moist Earth I allow but small Tillage in October, only to remove the Weeds and stay to give them a large one at the end of April, or beginning of May, when the Fruit is persectly Knit, and the great Moi-

Rain-

Vol. I. The Complete Gard'ner. 29

Rain-water seldom sinks above a Foot deep, but water of Snow Two or Three Foot, as being much heavier than Rain-water, and as it melts slowly and by degrees from the undermost part of the Mass of Snow, so it soaks with more ease, not being hindred by the Wind or Sun.

Therefore I dread much Snow upon strong moist Grounds, and order it to be remov'd from about the Fruit-Trees. So in dry Earth I gather it as a Maga-

zine of moisture to the Southern Expositions,

CHAP. XXII, and XXIII.

Of Amendments, or Improvements and Dungs,

Mendments are a bettering and improving of Earth, which improvement is made with all forts of Dungs, according to the temper and employment of the Earth. As for Instance there must be a great deal of Dung to produce Pot-herbs, which grow abundantly in a short time, and quickly succeed each other in a small compass of Ground. On the other side, Trees require but little or none for their Nourishment, because being so long a growing, they make but inconsiderable productions, compared to the Ground they take up; and the they remain long in the same place, yet by the help of their roots, which stretch to the right and less, they make a shift to pick up far and near the nourishment that is fit for them.

Now fince the great defects of Earth are too much moisture, coldness, and heaviness, also lightness, and an inclination to parching, so amongst Dungs, some are fat and cooling, as that of Oxen, and Cows; others hot and light, as that of Sheep, Horses, and Pigeons, Sc. And whereas the Remedy must have

Virtues

Virtues contrary to the Distemper it is to Cure; therefore hot and dry Dungs must be us'd in cold, moist, heavy Earths, and Oxen and Cow-Dung in lean dry

light Earths, to make them fatter and closer.

Not that these two sorts, tho' the principal are the only materials for amendment of Earth; for upon Farm-Lands, all sorts of Stuffs, Linen, Flesh, Skin, bones, Nails, Hoofs of Animals, Dirt, Urine, Excrements, Wood, Fruit, Leaves, Ashes, Straw, all manner of Corn or Grains, Soot, &c. In short, all that is upon or in the Earth (except Stones and Minerals) serve to amend and better it.

'The rest of this Chapter our Author makes use of in Philosophizing, which is little to our purpose, who have regard only to his experience, and matter

of fact; we proceed therefore to that of Dungs.

Of Dungs

In Dungs there are two peculiar properties; one is to fatten the Earth, and render it more Fruitful; the other to produce a certain sensible heat, capable of producing some considerable effect. The last is seldom found but in Horse and Mule-Dung, newly made, and still a little moilt; which indeed is of wonderful use in our Gardens in the Winter; it then animating and enlivening all things, and performing the Office which the heat of the Sun does in Summer; for being laid in Couches, it affords us all the Novelties of the Spring; as Cucumbers, Radishes, small Salads, and Melons, and all these long before Nature can afford them. In great Frosts it supplies us with Greens and Flowers, and which is very rare, early Asparagus.

When 'tis old, the heat being wholly past, but not rotten, it preserves from the Cold what the Frost might destroy, and therefore 'tis us'd in Winter to cover Fig-Trees, Artichoaks, Succory, Sellery, & all of great value in Gard'ning; and after all, being

rotten, it serves to amend the Ground.

The time for Amendments is from the beginning of November, till towards the end of March, because this Dung would be of no use in the Earth, if the Rains did not rot it; such as is us'd at other times, only grows dry and musty, and so far from being kind, that 'tis pernicious and satal to Vegetables; for where there is a large quantity of it, a multitude of large white Wortens breed in it, which gnaw all the tender things they meet with all. Now since the Winter is the only sat time for amendment, our Garden must not lose any part of it, neither minding the Quarters of the Moon, nor the Winds, whatever they be, they being only troublesome and usless Observations; and sit only to set off a visionary and talkative Gardner.

Sometimes there is a necessiry of Dunging largely, and pretty deep in the Ground, and sometimes is

enough to turn the top lightly.

I look upon Sheep's Dung as the best of all Dungs, and most promoting fruitsulness in all forts of Earth, the Treatise of Orange Trees will shew more particuly how I value it above all others; La Poudree, and the Dung of Pigeons and Poultry I seldom use, the one is too stinking, and the other is sull of little Fleas very prejudicial to Plants.

The Leaves of Trees rotted in some moist place, are rather Soil than Dung; and are better spread to secure Earth from parching, than to warm the inside

of it.

Terreou, or Soils, that Dung, which having serv'd for Couches, or Hot-Beds, is consum'd to that degree, that it becomes a fort of Mould; which then is employ'd no longer for Dung to fatten, but like Earth for small Plants, that may be laid Seven or Eight Inches deep upon new Buds, for Sallads, Radishes

diffies, and Legumes, that are to be transported, or to remain, as Mellons, Cucumbers, hard Lettuce &c, about Two Inches thick. It is also laid over Earths new sown at Spring, and in Summer, when they are too dry of themselves, and are subject to harden and chop by heat, by which the Seed would dry up, and not be able to get thro' the hardness of the Linth; in such case, 'tis us'd to preserve the moisture obtain'd by Tillage, and Waterings, and to hinder the Birds from picking of the new Seeds.

Ashes of all sorts, would be of great use in Amendments, if we had enough of them; but that not being possible we use them only about the seet of some Fig-

Trees, and others.

Some value Turf for Amendments, but I look upon it as only fit to produce of it felf, not to make another Earth Fruitful. I have a great value for the Earth under the Turff, as 'tis new Earth, never wrought, and confequently fruitful, and good for Fruit-Trees; or elfe so, after the same manner as I have caus'd Dungs to be employ'd for deep Amendments.

CHAP. XXIV.

Whether it be proper to Dung Trees.

OR the Resolution of which Point, our Experienced and Learned Author proposes Five Queries to those Gentlemen who affert 'tis proper to Dung.' Trees.

1. Whether they mean all forts of Trees?

2. Whether Fruit Trees only ?

3. Whether, if Fruit Trees, they mean all in general, to preserve the vigorous, and recover the infirm?

4. Whether they have a Rule for the quantity of Dung to be allow'd each, and where it should be laid?

5. Whether

33

5. Whether they should be Dung'd in all forts of

Earths good and bad ?

After all the Answers that can possible be suppofed to be given to these Queries, he gives a full and convincing Confuration of them, as the effect of his many years great Experience, and thereby proving it wholly improper to Dung Trees; no not so much as the Infirm, of whom he gives the following Character, viz, An infirm Pear-Tree is not always concluded so, by reason of its producing yellow Shoots, fince some that are very vigorous produce Leaves of that colour; only they are fuch upon which some old Branches die, or such, of which the ends of the new Shoots wither, or produce none at all; or continue Scabby, full or Cankers and Moss, yet bloffom extremely but little of the Fruit knits, and that which does, remains small, stony, and bad. But when the Tree chances to produce large yellow Shoots, which often happens to some Pears grafted upon Quincestocks, which being Planted in a dry Ground, are notwithstanding in a good Condition; this defect of yellow Leaves, proceeding from tome of the principal Roots lying level with the Ground, whereby they are parched by the great heats of the Summer.

An account of the Discases of Trees he gives at

large in the Fifth Parts

CHAP. XXV.

What fort of Earth is most proper for every kind of Fruit-Tree.

HE Wildings of Pear-Trees, Apple Trees, even those call'd Paradice, Plumb Trees, and Fig-Trees, agree well with all forts of Earth, hot and dry, cold and moist, provided the Ground be deep enough, viz. Two Foot and a half, or Tree Foot

D

rig-Trees require much less; Quince-Trees thrive not in dry light ground, soon growing yellow? Almonds and Peaches thrive better in this than in strong Earth, which makes them too subject to Gum; such strong Earths are fitter for Plumbs, small bitter Cherries, Goosberries, Rasberry Bushes, &c. Vines thrive and produce better Grapes in certain dry Grounds, than in strong cold Earths; Cherries thrive pretty well

in light Ground.

Earth has not the same effect as to the good taste of Fruits, as it has to the vigour of Trees; for the Winter Bon-Chrestien, Petit Oin, Lansac, and Thorn Pear, &c. will be always insipid, and most of them stony, or mellow in Ground that is cold and most: whether grafted on a Wilding, or a Quince-Stock especially for Dwarf-Standards. 'Tis the same with Peaches and Pavies, &c. Those kind of Fruits require a pretty dry Ground, at least one that's well drain'd by Gutters, or contriv'd Descents.

In short, Trees are commonly vigorous in strong Earth, but the Fruit seldom so well tasted, as those we

find in drier Grounds.

Besides Tillage and Amendments, your Garden must be always kept clean, the Walks kept tree from Stones and Weeds, as likewise the whole Ground-The Trees should be always free from Cater-pillars, Snails, Moss, &c.

Having thus far gone upon the true Sense and Experience of the Author, we conclude this Second Part,

and proceed to the Third.

The End of the Second Part

OF

FRUIT-GARDENS,

AND

Kitchen-Gardens.

VOL. I. PART. III.

A Preliminary Discourse Shewing the Order, Method, and Design of this Part, chiefly relating to Fruit-Trees.

cellent as well as most Innocent Food, whilst it grew in Paradise; a Climate so benign, and a Soil so richly impregnated with all that the Influences of Heaven could communicate to it; so has it still preserved, and retain'd no small Tincture of its original and Celestial Virtue. And tho' it has, in this Degenerate State of the World, ceas'd to be the genuine and natural, as well as the most Innocent and wholesome Diet; (when the Days of Man were as the days of Heaven, Long and Healthful, and would yet approach them, had not Mens intemperance, wanton and deprav'd Appetites, substituted the Shambles, and Slaughter'd Flesh to debauch us yet after all the D 2

Inventions of the most luxurious, and voluptuous Epicure; the most Casarion Tables would want of their Magnificence, noblest Gust, and grateful Reelish without Fruit, and the Production of the Garden which gives the true Condiment, and most agreeable closure to all the rest. 'Tis from Fruit, and Salutaery Plants, that besides the Nourishment they yield cus) we receive the Sovereign Elixirs, prepard, and extracted by natural Chymiftry and Solar Fire, of Virtue to Attemper and Allay the Ebullitions of the Blood, and sweeten its Saline Acrimony in the hottest Climes and Seasons; and with their Cordial Juices, to Recreate, Chear, and Restore the exhausted Spirits, clog'd and disturb'd by what they have contracted from those , full Meals of Flesh, and groffer Aliments: Parents of a Thousand Diseases and Infirmities: So that the' pos-, fibly it might not by some be reckoned among the ab-. Dlute Necessaries of Life: it ought at least be number'd , among those Conveniences, without which we should lose an infinity of that Pleasure, and innocent Contentment, which feems in pity to have been left us, to Charm and Alleviate the Cares and Anxieties which have, , fince the Fall, both shorten'd and imbitter'd Life. And, if after all our Labour to Repair what the choicest and most delicious Fruit has been despoil'd of, since ir grew in Paradife (but which we find by Industry and Culture so far exalted and restor'd) it does not arrive to that Transcendent Perfection; much less do any Artificial Supplement, as have all this while usurp'd the Place of that our more Innocent, Primitive, and Natural Food, pretend to come in Competition.

It is then upon this Account, and with Reason, that Naturally all Men, Princes especially, and great Persons, have in all Ages and Civiliz'd Countries, endeavour'd to cherish and incourage the Culture of Fruit; and to have spacious Gardens and Plantations; not only curiously contrived for Pomp and Ornament

but furnish'd with varieties of the most beautiful choice, and delicious Fruits, as Ryal Adjuncts to

their stateliest Palaces, and Rural Estates.

We have already shew'd, now near some Fruits do (by the Gard'ner's skill and care) approach Perfection, superior to any the richest Mixtures, necessary to Food, Health, and Refreshment; nor is there perhaps in all Nature's Circle, vast as it is, wherewith to charm, and, at once, Content more Senses, than do some Fruits (perfect in their kind) us'd with Mode-

ration, and as becomes us in all things elte.

'To Illustrate this a little, let us but take a turn or 'two in a well contriv'd and Planted Garden; and fee 'what a surprizing Scene presents it self in the Vernal Bloom, diffusing its fragrant and Odoriferous Wafes, with their ravishing Sweets: The tender Blossoms curioully enamell'd; the varioully-figur'd Shapes of the verdant Foliage, dancing about, and Immani'ling the laden Branches of the choicest Fruit; some hiding their blush. 'ing Cheeke; others dilplaying their Beauties, and even Coursing the Eye to Admire; others the Hand to Gather, and all of them to Taffe their delicious Pulps. Can any thing be more delightful, than to behold an ample Square (in a benign Afpect, tapestred and adorn'd with fuch a gloriou Embroidery of Festoons, and Frutages, depending from the yielding Boughs, pregnant with their "Offspring and pouring forth their Plenty and Store, as out of to many Amalthean Horns? some tinctur'd with the loveliest White and Red; others, an Azurine-Purple; others strip'd with Incarnadine, as over a Tissue of Vegetable Gold, Colours of an Oriency, that mock the Pencil of the most exquisite Artist; and with which their native Beauty, Perfume, Fragrancy, and Tafte, gratifie and entertain more Senses at once, than does any , Sublunary Object, in all un-vitiated Nature besides.

No wonder then, if after all the enormous Expence and Treasure, that Princes and Great Persons ay out in Raising Superb and magnificent Structures, and Country Seats, (built for Pomp, and outward Elegancy) the Gardens be neglected, so as not to an-'iwer, or be but Contemptible; they are deserv'dly slook'd upon as Imperfect, naked heaps of Stone and 6 solitary Masses, defective and useless to all those lau-6 dable and noble Purposes we have enumerated; and 6 as other Bleffings which improv'd Nature, with fo bounetiful a hand, gratifies her Friends and Favourers; furnishing the Owners with so many useful, and highly neceffary Conveniencies, as sweetens their agreeable Food and Industry, with the most wholesome and in-"nocent Diversion; in a word, so has this part of Agriculture obtain'd; as not only to have been thought worthy the Contemplation and Recherches of the Profoundest Philosophers (as well as Poets and Orators) but of the Mightiest Potentates, becoming Souls great and large as was that of Solomon's in all his Glory. Can there then be any thing more Admirable, and 'indeed desirable (of not forbidden Pleasure) than to lee, not only the Fruit and Labour of our own Hands to thrive and prosper about our Habitations; but to inrich, and improve our Native Store with the acceffion of Foreign Countries, excellent, and confummate in their kinds; and to possess within our own Walls, all that is so Rare and Elegant? in short, a 'hansemly contriv'd, and well furnish'd Fruit-Garden, is an Epitomy of Paradise, which was a most glorious Place without a Palace; but so can no Palace be, without what so nearly resembles it, without a Garden: And now, that such it may be, is the Design " of the entuing Treatife; made Short, Easie, and Pleafant, as was the Labour of that delicious Spot; and to Free it from those almost infinite, and insupportable Incumbrances, with which this agreable, and (in it felf) Easie Art, has hitherto been clog'd and abus'd, deliver'd to us in so many Voluminous Work, as have been

been publish'd; but which, in truth, serve rather to Tire, Distract, and Discourage, than usefully to Instruct; In order to this, the Authors of this Epitome have endeavour'd to shew (besides the Designing, Dressing, Preparing, and Inclosing of the Ground) how to distinguish and Discriminate the several kinds of Fruit. and how to make the most Judicious Choice; of what Numbers to compose the Plantation; and in what Series. Order, and Method to place them; that they may fo answer to the several and respective Seasons, always to gratifie the Care and Culture of the Gardner, Lord, or Master of the Plantation, with what is most excellent of the several Kinds, in an un-interrupted Circle, and perpetual succession, from the beginning of the Year, to its ending; together with whatsoever else is requisite to continue, and maintain the Plantation in the condition and Perfection it ought to be: And this, with a frank and generous Communication of all that (by long Study, Experience, Labour, and no small Expence, they have been able to attain, without the 'least, Reserve or Self interest, as a willing Tribute which , they gratefully offer to those Great Persons, Noble and worthy Genelemen, who have honour'd their Profession and Employment; or shall at any time hereafter accept of their future Service, and in a word, for the Benefit of all in General. Lastly, we do with all deference, and just respect, pay our Acknowledgments to the late 'Illustrious Monsieur de la Quintiny, the most knowing Director of all the Fruit and Kitchen-Gardens of the Royal Family at Versailles; where by his Conduct and Direction, that August Monarch has, with such infinite cost and encouragement, outdone all that we Read of Ancient, or can see of Modern, in Horticulture's Magnificence, advanc'd to its utmost Acme and Perfection. In which undertaking they proceed in the following Method and Order.

First, Having first told you, that by Fruit here is

not meant any of those that creep upon the Ground or grow on Shrubs; as Cucumbers, Melons, Strawberries, Currants, &c. Which we intend to treat of in the Sixth Part: whose Subject is of Kitchen-Gardens. We shall only insist upon these here which grow upon perfect Trees, as of Wall Trees, Durarfs, or Standards.

Secondly, To the best Sorts are given the most ample and lively Description that possible may be fram'd, and likewise the aptest Names, and most received amongst the most judicious fort of Curiosos; which are commonly deriv'd from s me principal Qualities, wherewith they affect the Senses of the Eye and Taste, and consequently denote something of the Nature of the thing, of which they are the Names.

"The Author here mentions that he has tafted a"bove three hundred leveral first of Pears, different
"one from another, without finding above thirty that

" are Excellent.

Great Allowancies are to be made to the fickleness of Seasons, of which we are not Masters; as also of the Diversity of Scils and Cumates, which are almost infinite; and to the Na ure of the State of the Tree, which is sometimes good and sometimes bad; and lastly, to the Manner of Figure in which the several

Trees grow and produce.

They are all Points that require a great deal of Confideration, and very much serve to ballance the opinion of those that would judge of them. There are sometimes ill Pears to be found among the Virgolees, the Lechasseres, the Ambretts, the Thorn Pears, &c. And but scurvy Peaches among the Minions, Magdalens, Violets, Admirables, &c. and bad Plumbs among the Perdrigons; some bad Grapes among the Muscatts, and some bad Figs among those that are esteemed. This may perhaps altonish some curious Persons; but the in certain fort of Good Fruits, there may be some desective, yet it follows not from thence that the whole Kind should be rejected.

So that a Fruit may prove ill one year, or in such certain Expositions, which may have appear'd Good several years before. So on the other hand, that Fruit which was Good this year, was not to be endur'd for some proceeding years. It remains now that we only add some few other Cautions and Remarks worth your Consideration, and so proced to the Treatise it self.

the quick bearing of them, yet because it Contributes both to the beauty of the Tree and Fruit, it should

not be neglected.

Second, The time that Kernel Fruit-Trees require before they attain to a fit Age for Bearing, is one with another) about four or five years, the some advance sooner than others, as is specified in their particular Descriptions; yet in the succeeding Years they bear more plentifully than the Stone-Fruit.

Third, That Stone Fruit Figs, and Grapes are usually not above three or four Years before they bear confiderably, and in the fifth and fixth Years bear their full Crops; which they continue, if well order'd, and

in favourable places, many years after.

Fourth, In some Grounds in the same Climate Fruit will Ripen fifteen days or more before some others, not sar off from them, in Ground of a different Temper.

Fifth, The difference of Hot or Cold Summers does freal more confiderably forward, or fet back the same Fruits, of one and the same Climate and Season.

Sixth, Fruits of good Wall Trees ripen a little before Standards in every Garden, and those of Stan-

dards a little before those on Dwarfs.

Seventh, Among Wall-Trees, the Fruits of those in the South and East Quarters do comonly Ripen much about the same time, save only that the South has a little the start of other, and that those on the West

are later by eight or ten days, and those of the North

by fifteen or twenty.

These are Remarks in France, which the Author treats of: For the East and West walls come so early there, and the North-walls in such a Time after them. Yet we reject planting any thing against those North-walls to be eaten Raw; but only Pears for baking, Plumbs, Cherries, &c. for baking or preserving, Except some Cherries that come after the others.

Cold, heavy, moist Grounds produce indeed the Fairest and Largest Fruit, but the hotter, drier, and lighter Soils, the more Delicious and rich Tasted.

and especially of Grapes.

When Fruits are laid up to Keep, not only the Fruit of every fort, but of every particular Tree, and every several Exposure, is to be laid in parcels by themselves, that it may more precisely be known when each of them is Mellow, and how long they will keep; and that the different Effects of Grounds. Expositions, and Forms of Trees, may be the more exactly observ'd.

CHAP. I.

Of Standard Pears to plant.

Standard Trees do not at all accommodate little Gardens, as Dwarfs do; the shade of Great Trees being destructive to every thing else which we might plant there; we will therefore plant no Standards but in great Gardens; and here regard must be had to plant them at a good distance from any Walls, excepting those of the North.

Now for this purpose we should chuse Trees of those sorts of Fruits which are not very big, and yet are of great increase, and are good when they fall, that is to say, of some Summer Fruits, because their smallness preserves them from bruifing, and their ripeness which loosens them from the Tree makes them fit to be eaten presently with Pleasure, when any of them happen to be batter'd in falling. Or else,

We should chuse those kinds which hold fast by their Stalks, and such whose Fruit are very hard in themselves, as are the small Winter Fruits, and bakeing Pears, so that they are not easily shaken down by Winds, nor when they fall, so apt to be much endamaged thereby,

Among the Summer Fruits proper to be planted in the form of Standard Trees, are comprehended the Russelet, the Cuisse Madam, or the great Blanquet, or the Musked Blanquet, the Musked Summer Bon Chresien, the Bourdon,

The Complete Gard'ner. Vol. I.

Bourdon, or the Musked Rebert, the Pendar, or the melting Pear of Breast, and in every large Plantation may be added some Summer Bon Chretiens, some Admiral Pears, &cc. For the Fruits of Autumn may be chosen the Lansacs, Vine Pears, Russellins, &cc. And for Winter Fruits, the dry Martin, the Ambret, the Winter Russellet, the Ronvil, and perhaps some Bezi de Caissoy Trees and in fine, for Fruits to bake, preserve, &c. the little Cerleau, the Franck Royal, the Angober, the Donvillee.

There we have about twenty four forts of Scandard Pear Trees to plant prosperously enough in our Gardens; but because in important places, as for Example, in fine Kitchen Gardens, bakeing and preferving Fruits are not confiderable enough to be allowed any room, and because they are expedient for all those that conveniently can, we may have some of them in seperate Orchards, defigned only for Finit, regether with all forts of Cherry Trees, Agrices, Biggaroes, Guines; with all forts of good Apples, Pepins, Calvils, Apis, Fenouillees, or Corpendus, &c. with some good forts of Plumbs, viz. of Damask Plumbs, of all forts of Mirabelles, dispred Damaik, &c. and lafily, with Mulberry. Trees, Almind Trees, Azerol, or Garden Ham Trees, &c. Therefore fince for thefe reasons, Fruits for Bakeing, &c. may be planted elsewhere, far off from our Kitchen Gardens, we should in their stead multiply some of the best of our Summer and Autumn Fruits; tho' a Summer Pear Tree that has been planted ten or twelve Years, is capable of yielding to great a quantity of Fruit of its kind, that 'twill be all we can do to fpend them before the Rottenness (that follows close after the Ripe-

Vol. I. The Complete Gard'ner. 45

Ripenels) surprises them, which makes them good for nothing. Soon out of other areas

And therefore when we are contriving Plantations of Fruit-Trees, we should still remember when we intermix in them any Standard Trees, that we must proportionably diminish the number of Dwarfs Trees, which we should otherwise be oblig'd to have of the very same kinds.

"Tis rot amiss to add here this Caution, that in respect of these Standard Trees, it is good in planting them to leave them some of the Branches of their Tops which they had when in the Nursery Garden, because they will bear Fruit to much the sooner, and because the height of their Trunks is not so exactly regulated as that of the Dwarf Trees; whether that heighth begin a Foot higher or lower, their shape will be never the less comely for that; and it is always a considerable advantage, which these fort of Trees may be made to afford us, by advancing their Fruitsulness, which we can hardly ever draw from the Dwarf Trees.

In places that are much exposed, or near the High ways where People pass, we ought to have this forecast, not to plant any Fruit there that is entable whilst on the Tree, otherwise its certain all the Fruit that will come to the owner from thence will be only a great deal of vexation, and little else.

As for what concerns the Plantations of Pears or Apple Trees for Syder, or Perry, the Trees may

Vol. I. The Complete Gard'ner. 46

may be planted at threescore or threescoreand twelve Foot apart one from another, because that proportion hinders not the Grounds in which they grow, at least for several Years together, from being sown yearly with good Corn; the plowing up, and other Culture used for the latter, extremely contributing to the well cultivating of the other.

Vol. I. PART III.

CHAP. I. II.

Of Pears.

La Bon-Chretien de Hyver.

His is justly preferr'd before all others. The Bonbeing of greater Antiquity, and has Cretiens. Carried this illustrious Name for many Ages. It's Noble to behold, by reason of it's long and Piramidical Figure, being usually five or six Inches Long, and three or four Inches Thick, and of a pound weight or more; nay sometimes above two pound. It's naturally Yellow, with a lively Carnation Co-

lour, when well Expos'd.

It lasts very long on the Tree, and endures the longest afterwards in perfect Goodness of any other Pear.

'Tis good Stew'd or Bak'd, if gather'd before it's full Ripe; but when 'tis come to Maturity, and the Ground good and well cultivated, it will continue Mellow for some whole Months together.

The Pulp eats Short, but Tender enough. Its Tafte agreeable, and Juice lugar'd, and a little perfum'd.

It does best against a South-wall? but the our Author adviseth to Plant them Dwarfs in small Gardens in France; yet the good Success of them in that manner

is to be doubted in England

Some Persons make different sorts of Bon Chretiens, as the Long, the Round, the Green, the Golden, the Sattin, &c. but they are all one and the same Fruit; only the Difference of Soils, Expositions, Seasons of the Year; and Condition of the Tree, may make great alterations both in Colour, Shape, Goodness, &c.

It should be Grafted on a Quince stock, because on a Free-Stock the Fruit grows spotted, small, and crumpled. 'Tis in Perfection in February and March.

La Burree.

The Burre. HERed Butter Pear or Ambroise, or Isambret, the Gray Butter and Green Butter Pears are all one, only difference of Soil, Exposure, Season, &cc. (as mentioned in the Bon Chretien) may occasion the Difference; also the Stock they are grafted on, either Free Stock or Quince, cauleth great alterations; but it does well on either. It's call'd the Butter Pear, because of it's smooth, delicious, melting foft Pulp.

Its Body is large, and of a beautiful Colour and bears very well commonly every year; in all forts Vol. I. The Complete Gard'ner.

37

or never apt to be Doughy, or Insipid, or Mealy. It's feldom Ripe the latter end of September, and bears soonest on a Quince.

La Bergamutte.

It has a tender melting Pulp, sweet and The Autumn sugar'd, and has a little smack of persume Bergamor. it's a reasonable good Bearer; the middling sort of the mare as good as the biggest; it does well either on a Quince or a Free stock, and on Different Soils, and either tor Wall, Dwarfs, or Standards. There is no difference in Bergamors, but what consists in the Colour when the above the difference is indeed and

only; but then that difference is indeed real,

The common Bergamot is of a Greenish Gray. The Bergamot Swis is strip'd with Yellow and Green Streaks, which appears both in the Wood and the Fruit; but as to the Goodness of each, there is little Difference. The fize of both is alike, being sometimes three Inches in thickness; but usually one and a half, or two Inches. They both have a stat Shape, the Eye or Crown sinking hollow in, the Stalk short and small, the Skin Yellowish, and a little moistish when Ripe.

There are no latter Bergamots, as some pretend, only different Soils, Seasons, &c. sometimes make an alteration. The Tree usually grows scabby. If the Ground be good and light, they do best on a Free-Stock; but if cold and heavy, on a Quince. Ripe

in September and the beginning of October.

La Virgoulee.

The Virgoulee, otherwise call'd the The Virgoulee.

Bujaleuf, Chambrett, the Ice-Pear, Virgoulee.

goulese and Virgouleuse. It's pretty long and thick,

E 3 being

being three or four Inches long and two or three Inches in thickness; its Stolk short, fleshy, and bending; the Eye or Crown indifferently great and hollow; its Skin smooth and polisht, and sometimes colour'd? it's Green on the Tree, but grows Yellow as it Ripens; and, if gather'd at the proper time, is one of the best Fruits in the World.

The Tree grows very strong, its Pulp tender and melting, with abundance of sweet and sugar'd Juice, a fine rich Taste, and a plentiful Increaser.

I Ripens almost as soon as the Bergamote, and the sure holds good sometimes from the beginning of No-

wher to part of the Month of Fanuary.

agreeable to the Eye; and those that grow as exp is d, have an admirable Virmilion Blush.

It succeeds well either on a Free or a Quince Stock.

It's pretty long before it bears, and much of the

Fruit is apt to fall from the Tree before it's Ripe.

It lasts during the Months of November, December, and Fanuary.

La les Chessery and L' Ambrett?

The La Chaffery and Ambrett.

The La Cheffery, or or Besidery-saudry, compar'd with the Ambrett. These Two Pears have a Resemblance with each other; their Shape roundish in both, tho' the Ambrett be a little flatter, and has its Eye or Crown hollower and deeper sunk.

The La Cheffery has its Eye or Crown quite jetting out, and some of them retemble a Limon in shape.

Their bigness is much alike, of a middle size, about Two or Three Inches extent every way. They are alike in Colour, which is Greenish and Speckled a the the Ambrete is commonly the deeper Colour, and the La-Chessery lighter and yellower, especially when Ripe. Their Stalks are both streight and pretty long,

long, but the Le Cheffery thickest of the Two; they Ripen and Mellow together in November and December. and fometimes in January. Their Pulp fine and butterlike, their luice sugar'd and a little perfum'd, but their Perfume is agreeable and very delicious; the Le-Chessery has more of it than the Ambrett, and the Pulp of the Ambrett is a little more Greenish, its Kernels blacker, and its Skin feels usually a little rougher. The Le-Chesseries are pretty often bunched and warty; they differ very much in their Wood; for the Ambrete is very Thorny, resembling a wild Tree; the Le-Chessery is pretty slender, and shoots out some points. but not fliarp. The Ambrett on a bad Soil has its Fruit of a faintish Taste, and a secret dry Rotteness in many of them. The Le-Gheffery loves a dry Ground. The Ambrett is long before it comes to bear. They are both in Perfection in November, December and 34muary.

L' Epine D' Hyver.

This is a very fine Pear, and comes nearer to a Piramid, than a round Fi- The Winter gure; tho' no part of it is small; of a Thorn. bluntish point towards the Stalk, which is short and small. This Pear is almost all over of the same bigness, being about two or three Inches thick rowards the Head. It's much bigger than an ordinary Bergamott, or Ambrett, or Le Chassery. It has a Satin Skin, its Colour between Green and White, ripens usually with the Le-Chessery and Ambrett. It has a fine tender Butter-like Pulp, an agreeable Tafte, sweet Juice, and admirably Perfum'd. It succeeds well either on a Free or Quince Stock, it loves a Soil rather Dry than Moist. It's pretty long before it bears. Ripe in November, December, and January.

La Rousselett.

The great and small Russelets are all The Russelets. one; but the middle fize are the best: Those of the product of a Fat Soil are of a middling fize, handlome shap'd, more long than round, pretty thick Stalk, and somewhat long, Gray Colour, reddish on one side, and dark red on the other, with some greenish interlaced, which grows Yellow when Ripe. Its Pulp tender and fine throughout, Juice moist and agreeably perfum'd: it's good either Raw, Bak'd, Stew'd, or Preterv'd, or in liquid or dry Sweet-Meats; will prosper in any Ground, and may be planted either against a Wall, or as a Dwarf or Standard; bears larger and fairer Fruit, and in more abundance, against a Wall: Ic's no long laster, but soon grows foft and pappy: Ripe at the end of August and the beginning of September.

La Robine.

The Robine, or Pear Averat. or Mulcat The Roline. Pear of August, or Pear Royal, as it's call'd It's of the bigness and thape of a little at Court. Bergamott, between round and flat : Is Stalk pretty long, threight, and funk pretty hollow into the Pear; also its Crown or Eye is a little hollow or sunk in. Its Pulp breaks short in the mouth, but not hard; it has an excellent fugar'd and perfum'd Juice, and much admir'd by the French King. Its Colour Yellowish white, Skin gentle, and hardly grows fort at all, as almost all the Summer Pears do. Les excellent either Raw, or Bak'd, or in Sweet-Meats. The Tree Thrives every where, but its Wood sometimes Cankers, and is hard to be brought to bear.

Ripe in August and September.

La Crasanne.

The Cressan, or Bergamor Crasame, is of The Cressan the Nature and Colour of the Beurre, tho' distering in shape; being nearer like the Monsieur Jean, of disterent sizes, of Colour Greenish; growing Yellow when Ripe, and speckled almost all over with red spots; its Stalk long, pretty thick, bent and hollow set; Skin rough, Pulp extremely tender and butter-like, but not always fine; full of Juice, but sometimes accompanied with a biteing sharpness. It will keep a Month and not grow Pappy, and perisheth very leasurely: May be Grasted either on a Pear or a Quince Stock. Ripe in November.

La St Germine.

The St. Germine is very long and The St. Germine pretty big; some of them Green and a little Spotted, some pretty Red; but all of them grow very Yellow as they Ripen; Stalk short, pretty thick and bending; Its Pulp is very tender, and not gritty; sull of Juice, but of a little Limonish tartness, which pleaseth some and displeaseth others. It's supposed that a Quince Stock and a dry Soil gives it this slavour; the Tartness is usually in those that are first Ripe. It does best on a Soil moderately Moist, and on a Free Stock. Continues good during the Months of November, December, and January.

La Marquiss.

The La Marquis or Marchioness. On The La Marqiss a dry Ground it resembles in bigness and shape a fine Blanquet, or a middling Bon Chretien, but on a fat and moist Ground it grows very large; it's of a handsome shape, flat Head, little Eye, Crown sunk inwards,

wards, pretty big Belly, and handsomely slopeing towards the Stalk, which is indifferent long, thick, bent and hollow fet; its skin pretty rough, green Colour, flourished with flakes of Red like the Beurree: the Green grows Yellowish in ripening; the Pulp tender and fine. Tafte pleasing, full of Juice and much fugar'd, but somewhat Stony at the Core. It does best on a dry Soil. Ripe in October.

La Colmar.

The Colmar, otherwise call'd the Mannes Pear, or Latter Bergamot. This Pear does much Resemble a Bon Chretien, and sometimes like a fair Bergamot; Its Head flat, its Crown pretty great. and funk very hollow; its Belly little bigger than the Head, moderately lengthening, and grofly loofening it felf towards the Stalk, which is short, pretty thick, and bent downwards; it's of a spotted Green Colour like the Bergamot, sometimes a little Reddish on the Sunny fide, comes a little Yellow in December and 74. muary when Ripe; and sometimes lasts till February or March. Its skin is gentle and smooth, its Pulp tender. Tuice very sweet and sugar'd: It's an excellent Pear: but bad Soils and Seasons some times causeth its Pulp to be Gritty and Infinid. The Fruit falls eafily off by Winds, before its Ripe. Its Maturity is not to be taken from its turning Yellow, but when it yields to the Thumb. It's pretty long before it comes to Bear. It's in perfection in December, January and February.

Le Petit Oin.

Le Perir Oin. This Pear is call'd by the People of Anjou Bouvar, or Russelet Anjourby others, the Winter Marveil. Its of the bigness and shape of the Ambret or Le chassery, of a clear Green, a little spotted, and has a little touch of Yellow when Ripe, resembling a Midling

Vol. I. The Complete Gard'ner.

ling Bergamot, but not so flat: It's very round, and has its Eye or Crown jetting outwards, its Stalk small, pretty long, and a little bending and shallow fet; its Skin between rough and foft; its Body uneven and full of Bunches; its Pulp extremely fine and melting, and not gritty; its juice very sweet, and very much fugar'd and perfum'd: But notwithstanding these good Qualifications, it sometimes grows doughy and infipid, by accident of Weather, or moist Ground. Ripe in November and December.

La Louis Bonne.

It's shap'd much like the St. Germine, and The Lewalso resembles the Vert Longue, but not is Ben. quite so narrow pointed; some are much bigger and longer than others, but the least are best; its Stalk is short, fleshy, and bent; its Crown small and even with the Body; its skin smooth, speckled, and greenish, growing whitish afterwards; which happens not to the large ones: Its whiteness and yielding to the Thumb, argues its Ripeness; it's very fruitful, its Pulp tender, full of juice, sweet, and rich of Taste, and grows not pappy, provided the Ground be good; but a watery Soil makes the Fruit large and bad, and the Pulp oyly: Its Pulp generally hangs not together; the Fruit eafily falls off. It does best on a dry Soil. It's in Perfection in November and December.

La Vert Longue.

The Vert Longue, or Moule Bouche; The Vert Longue; the Name describes its Colour and or, Long Green Shape; an old Pear and agrees best Pear. with a dry Soil; bears very well; its Juice sweet and perfum'd, and delicate fine Pulp, withThe Complete Gard'ner. Vol. I.

out any grittiness; it has a very thin Skin, and is a good Pear. Ripe the middle of Odober.

La Lansac.

It's call'd also the Liebefrion: it's about the bigness of a Bergamos; the middle fize are best; its shape is between round and flat towards the Head, and a little longish towards the stalk; of a pale yellow Colour. fugar'd Juice, and a little perfum'd; fimoorh Skin. vellowish Pulp, tender and melting; its Eye or Crown big and even with the Body; Stalk threight, long, thick, and fleshy. The Tree on a dry Ground produceth its Fruit of a Cinamon Ruffet Colour, and very good; but on a wet Ground proves doughy and infipid. In Pertection about the end of October.

La Martin Sec.

It has an Isabella red on one fide The Martin fee. and a high colour'd red on the other: its Pulp eats short, and pretty fine: fugar'd Juice, and a little perfum'd. It may be eaten Skin and all, and as foon as gather'd. It's a great Increaser, and keeps pretty long, and agrees well enough with any Soil. Ripe about the middle of November:

Le Meffieure Jean.

The whi e and the gray Monsieur The Messieur fean. Johns are both one: It's subject to be stony or gritty, and therefore dislik'd by some; also its Pulp is rough and gross, it loves a Soil moderately moift, and a mild Summer, and tho' it grows large and fair, encreafeth mightily, and fucceeds almost as well on a Free, as on a Quince Stock,

Vol. I. The Complete Gardner. 45

flat shap'd, the Skin of the gray ones are rough, but the white ones smoother; its Pulp short Juice sugar'd, but somewhat gritty. Ripe about the middle of Ottober.

Le Portaille.

This Pear is samous in the Province of The Portaile Poileau. It's accused that its somewhat hard, stony, and gritty, and seldom comes to good but in that Province, and not eatable till it begins to rot; and that of many of them, but sew prove good: Succeeds best on a Free-Stock; Its Juice is sugar'd and persum'd; in Bigness, Colour and Shape, it resembles abrown Monsieur John: Mellow in January, and February.

La Saint Augustine.

It's about the Bigness and Shape of a fair Virgoulee, indifferent long and pretty big, gustine. Its Belly and lower part round, but somewhat lesser on that side and towards the Stalk; the Stalk is rather long than short, in some streight, in others bent, not hollow set, its Eye or Crown big and a little sunk inwards, of a fair Limmon Colour a little speckled, with a blush of red on the Sunny, side; its Pulp tender, but not buttery, has more vice than it seems to have: Some have a smack of Jowrishness, which gives an agreeable Relish; but others have none at all, or very little. Ripe in December.

Le Petit Muscat.

It's a good Pear when pretty large and, when it has time to grow to mellow and ripen well; it proves better being planted against a Wall, than a Dwarf, and would be more esteemed

Vol. I. The Complete Gard'ner. esteemed were it not so small; ripens almost the first

of any Ripe in July.

Le Gross Blanquet, & ou Blanquet Muske. La Blanquet Longue Queue.

The Great, the Little, and the Long-tail'd Blanqueis.

The Great Blanquet, differs much from that call'd the little Blanquet, and ripens Fisteen Days before it. It's the true muskt Blanquet; it's larger, and

not so handsomly shap'd as the leffer one; colours a little upon a Dwarf, has very short thick Statk, and hollow fet, its Wood Small, and in Leaf and Wood resembling the Cuisse Madam: but the Little Blanquet has its Wood thick and short.

The Long-tail'd Blanquet is a handsom Pear, its Crown pretty big and standing out, its Belly round. and pretty long towards the Stalk, which is also long, fleshy, and bending; its skin smooth, white, and fometimes a little colour'd on the Sunny fide, its Pulp between short and tender, very fine and full of Juice. fugar'd and pleasant, but somewhat gritty, and grows doughy when too ripe.

C beginning of July. The Gross Blanquet end of July. The Petit Blanquet The Blanquet Longue Queue,

La Cuisse Madam.

It's a kind of Russelet in Shape and Co-The Cuisse Malour, its Pulp between short and tender, dam, or Ladies very Juicy, and a little muskt, very Thigh. pleasant when full ripe; this and the

Blanquets are the first Pears that are reasonably good: it's pretty long before it bears, but afterwards produceth abundance. Ripe the beginning of July.

La

La Cassolette:

This Pear is also call'd the Friolett or Muscat verd; it's a long Grayish Pear, near as good as the Rebine, both for Pulp and Juice and other Qualities, save only that it's apt to grow soft; it's ripe about the middle of August.

Le Muscat Robert.

It's also call'd the Queen-Pear, Maidenpear, Amber-pear, Maiden of Zantoigne, &c. Robert.
its Pulp is tender, and Juice indifferently
Musked, and much Sugar'd; it's a very handsome
Pear, it's about the bigness of a Russeles; its only
fault is, to have a little Stony or Gritty substance,
and lasts but a little while; it's a great Increaser, and
ripe the middle of July.

La Poire de Vigne.

The Vine-pear, or Damfel pear by fome The Vine failly call'd, the Petit Oin; it's Gray, Red-Pear. ifh, Round, and pretty big; has a Stalk extream long; its Pulp is neither Hard nor Buttery nor Tender; and herein differs from all other Pears, having a flattish, glewy Pulp, and often doughy: Ripe in Ottober.

La Poir sans Peau.

This is also call'd the Guine flower, and Hafty Ruffelet; it's longish shap'd, and Ruffet-cotoru'd; it's a pretty Pear; Juice Sweet, tender Pulps, and not Gritty. It's a good Pear, and usually Ripe about the Twentieth of July.

La Muscat Fleuri.

This is also call'd the Long-tail'd Muscar The flowof Autumn; it's an excellent round reddish ering Mus-Pear, of indifferent bignet; it's Pulp tencat. der and fine, rich Talte, and may be eaten greedily like a Plum, or a Cherry. Ripe about the middle of October.

Le BonChresien d' Este Musque.

This Pear seldom comes to good, but The Muskon a Free Stock, and makes a fine Tree; ed Summer the Fruit is excellent, of agreeable shape, Bon-Chreand reasonable bigness, about the largeness tien of a fair Bergamot; its Colour is White on the one fide, and Red on the other; its Pulp between short and tender, full of Juice, and persum'd: Ripe the latter end of August and September.

L'Orange Vert

It's pretty big, flat and round, its Eye 7 be Green Ohollow its Colour Green, and fring'd range Pear. with Carnation; its Pulp short, Juice sugar'd, accompanied with a particular Perfume; bears abundantly on a Dwarf: Ripe in August.

La Doyenne, Ou, St. Michel.

It's about the bigness and shape of a gray The Deans Beurre; its Stalk thick and short, very Pear, or, smooth skin'd, greenish Colour, which St. Michel. becomes Yellow when Ripe: It is a right melting Pear, its Juice sweet, but of no very good relish, tho' it be a little persum'd: Its Pulp easily grows Vol. I. The Complete Gard'ner, 49

grows, and as it were fandy; it should be gather'd pretty green, and eaten before it's quite Yellow, and then it may be reckon'd a reasonable good Fruit. It's fruitful in all Soils; beauisul when ripe, and bears soonest if Grafted on a Quince: Is in perfection the latter end of September and October.

La Besi de la mote

This is a new Pear, and resembles pretty near a large Ambree, only that it's spotted la mot. with red. Ripe at the end of Ollober.

Le Bourdon.

This Pear much resembles the Muscat Robert in Bigness, and in the Nature if its Pulp, Taste, Persume, and time of Ripening; which is about the end of July. and beginning of August.

The Bourdon; or, Humble Bee.

L' Espargne.

It's a red Pear, indifferent big, and very long, and (as the Translator expresses it) a little vaulted in its shape, its Pulp tender, but a little sowrish; is more beautiful than good. Ripe at the end of July.

La Magdelene.

It's indifferent large, greenish, and pretty tender, shap'd almost like a Bergamot; must be gathered before it grows yellow, otherwise it grows Doughy. Ripe the beginning of July.

P.

Le Sucre Verd.

The Name describes its Juice and Colour; it much resembles in shape the Winter Thorne, but smaller; its Pulp is very buttery, Juice sugar'd, and Taste agreeable; the only fault is, that 'is a little strong towards the Core. Ripe the end of October.

Le Bugi.

In Colour and Bigness it somewhat resembles an Ausumn Bergamot, but not so flat towards the Eye or Crown, and a little longer towards the Stalk; It's greenish, speckled with little gray Specks, which come yellowish in ripening; its Pulp is both tender and firm, and eats pretty short, but sometimes grows doughy when too ripe before it's gathered; 'tis very juicy, and has a smack' of Sowrishness, but a little Sugar will remedy that defect. Ripe in February and March.

La Double Fleur

It's very beautiful, large and flat, Stalk long and straight, Skin smooth, blush-co-lour'd on the sunny side, and yellow on the other; If it be much handled, it turns black after a few Days. Some Persons love it raw, and like its Pulp and Taste; but it's the best for Composes, or wes Sweet-Meats, and therein excels any other Pear, it has a marrowy Pulp, and not gritty at all, abundance of Juice, and colours well over the Fire. It's in Perfection in March.

Le Franc Real

Is large, round, and yellowish, The Frenck Royal, specked with little reddish Spors, Winter Finor. Thort Stalk, it's a great bearer.

Ripe in January.

L' Angobers

It's pretty big and long, blush-colour'd on one side, and a grayish Russet on the bar other, the Tree in growth resembles the Boure, and the Frust much like it.

The Ango

La Besiders.

Is indifferent round, about the bignes The Bestof a large Tennis Bill, of a yellowish and deri. whirish green Colour, the Stalk pretty streight and long; it's a bakeing Pear, and but an indifferent Fruit. Ripe in Glober and November:

Le Gross Oignonett.

Is also call'd the Amtre Roux, and The great Onion. Red Wonder, and King of the Summer; it's pretty red colour'd, round and indifferent large, Ripe in July.

La Poir de Ronville.

In Bigness and shape is much like a fair The Ronville Russelet or Russelin; its Eye or Crown pretty hollow, and sunk in, the belly usually bigger on one side than the other, but yet every where pretty big; handsomely sloping towards the Stalk, which is of a midling thickness and length, and not hollows

52 The Complete Gard'ner. Vol. I.

low fer, the Colour lively on one side, and very yellow on the other; when mellow, the Skin is slick and Sarin-like, its Juice sug ar'd and agreeably perform'd, and the Pulp eats short. It's faults are that 'tis small, somewhat hard, and a little gritty. Ripe in January, and February.

Le Bon Chritien d' Espagne.

Is a great thick long Pear, of a hand-The Spanish some Piramidical Form, resembling here-Bon Chretien. in a Winter Bon Chretien; it's of a bright red Colour on one fide, speckled with little black Specks; on the other fide of a whitish yellow: Its Pulp eats very short, Juice usually sugar'd, and indifferent good when on good Ground, and when it arrives to perfect Ripenels, which it continues to to be fometimes from the middle of November 'till Fanu. ty? it would be more effeem'd if other melting Pears were not then in prime. The Author, after Twenty Years Experience, found its Fulp to be harst, gross, and stony, especially in moist Summers, or cold Ground; 'tis but an indifferent Pear, but looks well in adorning Piramids. In Perfection in November, and December.

Le Salviati

The Salviati. This Pear much resembles a Besideri in Shape, but not in Colour; It's pretty big, round, and indisferent long, small Stalk, which is set in a little hollow, its Eye or Crown a little hollow; the Colour is of a yellowish Russe white: Those that have great red Streaks, have a pretty rough Skin: but those that have none of that red, are soft enough; Its Pulp is tender, but not fine, the Juice which is but little, is sugar'd and persum'd, resembling the Robine

Vol. I. The Complete Gard'ner. 53 in Taste. 'Tis an indifferent good Pear. Ripe in August, and September.

Le Blanquet Musques

It resembles pretty near the Muscae Robert in Bigness and Shape, has a fine Skin, of a pale yellowish Colour a little ting'd with red on the Sunny

The musk'd Flanques, or, white musk'd Pear.

fide, the Pulp is a little firm, and not without some earthy and stony matter, its Juice very sweet and sagard, Ripe the beginning of July.

La Paftourelle.

Is much of the Bigness and Shape of the St. Lezin, or of a fair Russeles; its Stalk bent, and hollow set, and of a midling length and thickness, the Skin is be-

7 be Pastorel, or, Shepherds Pear.

tween rough and smooth, growing a little moist as it Ripens, its Colour on one side yellowish, cover'd with Russee Spots; having on the other side a little blush of red, its Pulp very tender and melting without any Grittiness, but the Juice a little sowrish: 'Tis but an indifferent Pear. Ripe in December, and January.

Le Beurre d'Angleterre.

Is more long than round, refembling in Shape and Bignels a fair Vers Longue, tho' not in Colour, its Skin smooth, and of a greenish grey Colour, full of ruffer

The English Beurree, or, Butter Pear.

Specks, the Pulp very tender and Eutrer-like, and full of pleafant Juice; but is commonly mealy, and easily grows fost, even upon the Tree; and because it comes in with the Vers Longue, Petit-Oin, and Lang-fac, (being better Pears) it's less esteem'd. Ripe in-November

La Citron d' Hyver.

The Winter Limon. It resembles in Shape and Colour a middle sil'd Limon; its Pulp very hard, stony, and gritty, but sull of Juice, and extremely musk'd. Ripe in January, and February.

Le Chat Brule.

The Casburnt
Pear.

It resembles in Shape and Bigness the
Martin Sec, but differs in Colour, being
on one side very russet, on the other pretty clear, its Skin smooth, Pulp tender, but a kind of
wildish Tenderness, inclining to be Doughy, has but
little Juice; in taste resembling the Bessery; it has a
very strong Core: A Fruit of little value. Ripe in
Ottober, and November.

La Ruffelet d' Hyver.

This Pear differs very little or nothing Russeller. from the Martin Sec; but there is another fort of a greenish Colour, growing yellow as it ripens, its Pulp between tender and short, but ful of Grittiness, is very juicy, and tweet enough, were it not for its greenish, wildish Tast. Ripen February.

La Pair de Livre.

Is a very big weighty Pear, the Skin pretty rough, and of a dark Russet Colour Stalk short, and its Eye or Crown hollow, makes excellent Compotes, or Sweet-Meats, either stew'd, or done any other way. Ripe in November, and December.

La Rousseline.

Is in Shape like the Rousselet, of a very light Isabella Colour, like the Martin Sec; The Russeline its Pulp tender and delicate, Juice very much sugar'd and persum'd. Ripe in October.

La Bouchet,

Is large, round, and white, like the Besidery; some are about the biguess of a midling Bergamot; others are bigger than a large Cassolles, its Pulp fine and tender, and Juice sugar'd. Ripe about the middle of August.

La Pendar

In Pulp, Juice, and Shape, is like the Cassolet, but a little bigger; its Wood also ing pear. differs. Is ripe about the end of September.

La Poir Chat.

Is shap'd very like a Hen's Egg, or almost like the Martin See, its Stalk is The Cas Pear. different long and thick, the Skin very smooth, sattin'd, and dry; the Colour a very clear or light Isabella, its Pulp tender and buttery, and Juice indifferent sweet; its a pretty good Pear. Ripe in Ostober.

La Bess de Cutsso.

It's a little Pear, about the bigness of the Blanques, yellowish, and all over full of Russes Spots; its Pulp tender but doughy, mixt with much earthy and story matter, the Juice not very pleasant, and in Tast refembles

The Complete Gard'ner. Vol. I

sembling that of Services; 'tis but an indifferent Pear-Ripe in December and Fanuary.

La St. Francis

The St. Francis. Is good only baked or preserved; it's indifferent big, and very long, yellowish, and has a very thin Skin.

L' Orange Musquee.

The Musked Is indifferent large, flat, and pretty orange Pear, much ting'd with red, Stalk long, its Skin usually spotted with little black Spots, the Pulp pleasant enough, but a little gritty, Ripe the beginning of August.

Le Gross Fremont.

Is indifferent big and long, and of a yellowish Colour, Juice sweer, and a little persum'd, it's good only bak'd or preserv'd. 'Tis in Persection in December, and January.

La Carmelite.

The Carmelite. Is large and flar, gray on one side, and a little ting'd with R d on the other, and in some places sull of pretty large Spots. It's ripe in March.

La Poir Roje.

The Rose Pear. Is indifferent large, flar, and round, its Stalk very long and small, and Pulp eats short. Ripe in August, and September.

La Callio Rosat.

Is almost of the Colour, Bigness, and Shape of an ordinary Monsieur Fean, but a little rounder, has a very short Stalk, and set hollow like an Apple; it's Pulp eats short. Ripe in August and September.

La Villaine d' Anjou.

It's large and flat, of a yellowish gray
Colour, and has a short eating Pulp. Ripe
in October.

The Villain of
Anjou, & c.,

Le Gross Queue.

Is stony and dry, and therefore The tail'd Pear. slighted; the by some esteem'd, because it is much persum'd; it's yellowish of Colour, and of competent Bigness. Ripe in October.

OF

FRUIT-GARDENS,

AND

Kitchen-Gardens.

VOL. I. PART. III.

CHAP. III.

Monsieur de la Quintinye's Discription of Peaches, Plums, and Cherries.

La Peche de Troy.

The Troy Peach. Is a very good little Peach, but not very constant in Bearing, and is subject to be pester'd with Aner; it's round, having a little Teat at the end; the colour very much ting'd with red, the Flower pretty large, tho' the Tree is but small.

La Violet Hastive.

Is an excellent *Peach*, has a most delicious and persum'd Pulp, a vinous and noble Taste; its only fault is that 'tis not large enough.

The Violet Hasting, or, forward Violet.

L' Admirable.

This Peach has almost all the good The Admirable Qualities which can be desired in a Peach, and has no bad ones; it's very round and large' and of a lovely Colour; a sirm, sine, and melting Pulpa a sweet and sugar'd Juice, a vinous, rich, and exquisite Taste, is not subject to be doughy, remains long on the Tree, a great Increaser, its Stone is but small, those that ripen last on the Tree are best, for 'tis very subject to drop its Fruit half ripe, greenish and all downy, and then it loseth all its goodness; to prevent which, the Tree may be prun'd and cut very close so the Branches which shoot out will be sairer and sounder, and the Fruit better.

La Mignone.

Is the most beautiful of Peaches that is, it's very large, very red, sattin kin'd, and round; ripens the first of those of its Season, has a firm and a very melting Pulp, a very small Stone; but the Taste is not always the richest nor briskest, being sometimes a little slat and saint.

La Belle Chevereuse

Is a beautiful Peach, and ripens next after the Minion; it's hardly inferior to any in Largenets, beauty of Colour, and The Bell Chevereuse, or, Goat Peach.

good

good Shape, which is a little longish; its Juice is abundantly sugar'd, and well relished, and is a great Increaser: But sometimes it grows doughy, when suffer'd to be too ripe on the Tree, or when it grows on a cold moist Soil.

La Nives.

Is a very fair large Peach, of a fine Colour both within and without, which
renders it most a greeable to look upon;
its Pulp and fuice are very good, a
finall Stone, and the Tree is a great bearer: 'ris not
quite so round as the Minion and Admirable, but
pretty near it when the Fruit grows on a sound
Branch, otherwise it's a little horned and longists.
Ripe about the Twentieth of September.

La Purpres.

The Tree bears in great abundance (and The Furple for that respect may be presented before the Burdine, the that be the better Peach) one may know the Colour thereof by its Name, it's of a brown dark red Colour, which penestrates much into the Pulp, which is of a very vinou-Taste; it's very round and indifferent large, and the Pulp pretty fine, Taste rich and exquisite.

La Magdelene Blanche.

It's an admirable Peach when planted in The white a good Soil, and well exposed, but very Magdelene. Subject to be injured by Ants. Some Gardners believe that there are two sorts of them because some bear well, and others but little; but the Flower of each is alike, which is large, and has a little blush of red; also the Leaf of both agrees, be-

ing large, and very much indented; they also ripen at the same time, which is towards the end of angul; and agree also in Colour, Bigness, Shape, Juice, Taste, and Stone: Both of them are large, round, and halfstat, very much painted with red on the Sunny side, and not at all on the other; a fine Pulp, a sweet and a sugar'd Juice, a rich Taste; no red about the Sone, the Stone in both of them is short, and almost round; they both produce goodly Trees, and the difference is Judged to proceed only from the more or less Vigour of the Stock they are buded.

La Persique.

Is a marvellous Increaser, and of an admirable Taste; it's longish, and has all the good Qualities that can be wisht for when the Tree is healthy, and in a good Soil, and well exposed and as generally Peach Stones resemble the shape of the Fruit, so this of the Persique, is a little longish, and the Pulp next thereto is but very little ting'd with red; it ripens just after the Chewereuse, and a little before the Admirable.

La Violette Brugnon.

Is an admirable Fruit when it comes to tuch Maturity as to grow a little shrivell d and wrinkled, the Pulp is reasonably tender, or at least not hard, it's pretty much painted with red about the Stone, the Juice and Taste extremely delicious.

La jaune tardive Admirable.

Is a Malecotoon, but it wholly resembles the Admirable Peach, both in Shape and Bigness, so that it may well be called the yellow The yellow later Admirable.

Admirable,

Admirable, from which it differs in the yellow Golour both of its Skin and Pulp; they are both colour'd red on the Sunny side, and the red pierceth a little more about the Stone of the yellow one, than about the white; it's of good Taste, but a little subject to be doughy.

La Violet Tardive, ou, Marbree.

The later Violes, or, marbled PeachIt has a vinous and delicious Tafte, and when it ripens well, it surpasses all the rest; it requires very much Hear, is a little bigger than the ordinary Violet Peach, and not so much colour'd all o-

ver with red as that, and borrows the Name of Muble, because it's usually whipt or strip'd with a violet red. It's apt not to ripen well, and to chap and burst all over, when the Autumn proves too cold or moist

La Bourdine.

The Bourdine. It's an admirable good Peach, not inferior to any of the former, only it's not quite so large as the Magdelens, Mignions, Chevereuse, Persiques, Admirables, Nivets, &c. tho' iometimes it comes very near them. The new-planted Trees are a little tedious before they come to bear, but when once they begin, they are extremely loaden with Fruit, which occasions its Peaches sometimes not to be so big as they should be; but if some of them are taken off about Midsommer, and only a reasonable number left on, they will grow large enough; they are the roundest, best colour'd and most agreeable Peaches to look on, that we have, and their inside is as good as it appears outwardly.

L' Avaunt Peach.

It begins to ripen a Month before other Peaches, and comes to Maturity at the very beginning of July it's small and roundiff, with a little Teat at the end; is so yery pole that no Sun can colour it red.

The forward, or, white Nutmeg.

very pule that no Sun can colour it red, tho' it shine on it never so warm; the Pulp is fine enough, but very subject to grow doughy, and has not so brisk and rich a Taste as most of the others have; is better for Composes or Sweet-meats, than raw; its Flower is large, and of a pale yellow, makes no handsom Tree, and the most pester'd with Ants of any.

La Peche d' Italy.

Is a kind of hasting or forward Persique, and resembles in all things the Persique; its Bulk is noble, the Figure longish, with a little Teat at the end, the colour a fair deep Carnation, its Taste good; but it ripens about Mid-August, which is full Fiscen days before the other.

La Peche Royal.

Is a kind of Admirable, but comes later, and of a darker red without, and a little more ting'd with red near the Stone than that, otherwise it's perfectly like the Admirable; and is an excellent Peach.

The Royal Peach, or later Admirable.

La Rosanne.

It refembles the Bourdine in Shape and Bulk, and differs from it in the colour of its Skin and Pulp, which in this latter are

The Rofanne Peach.

yellow; both of them take a strong Tincture of red

64 The Complete Gard'ner. Vol. 1.

from the Sun, viz. a very dusky red; this Peach is very fruitful and well tasted, the only fault is, that 'tis apt to grow doughy when too ripe.

L' Alberge rouge.

Is one of our prettiest Peaches, for its vinous and rich Taste, if ripe enough; otherwise its Pulp is hard; 'tis no bigger than a Troy Peach, and much like it, but seems to be more colour'd with red; the only fault is, that 'tis not large.

La Magdelena rouge.

The red Magdelen, or, double Troy Peach.

Is round, flat, and finking, very much colour'd with red without, and pretty much within; it's indifferent large, and apt to grow double and twin-like, which hinders it from producing fair

Fruit; the Flower is large and high colour'd, its Pulp not very fine, but Taste good enough, but not near so good as those before mention'd, tho' in some places it improves both in Bigness and Taste extremely.

La Belle de Garde.

The Bell-gard Peach. Is a fair Peach, a little fooner ripe; and less tinctur'd with red both within and without than the Admirable, its Pulp a little more yellowish, but the Taste not quite so rich; otherwise in Bulk and Figure it might be taken for an Admirable, but produceth not so good a Tree as that.

La Pavie Blanch.

In the outlide it differs not at all from the white Magdelene, only in opening it we find The white it a Pavie, (viz. cleaving to the Stone;) it has a firm Pulp, and a good brisk Taste enough, when full ripe.

La Pavie Rouge de Pompone.

Twelve or Fourteen Inches about, of a very lovely red Colour; and nothing is more delightful to behold, than when a good Wall Tree has a good quantity of them; when they come to ripen well, and in fair weather, a Garden is much honour'd in being adorn'd with them, the Hand well fatisfied to hold them, and the Mouth exquisitely pleas'd in eating of them.

La Blanche Andille.

Is a great increaser, fair to the Eye large, round, and flat, takes a lively Colour in the Sun, but no red within; it's indifferent good, when not suffer'd to ripen too much on the Tree, for then it grows doughy.

The Complete Gard'ner. Vol. I.

Colet black.	Brugnole. Great Violet Tours Damsk. Rhodes Plum.
Black Plums.	Late Forward Damask. Musk'd Damask. Pigeons Heart.
Green Plums	Green Damask, Castellan.
Red.	Gray Damask. Cherry Plum. Prune Morines. Datilles, or little Dates.

As for the flicking to the Stone in Plums, 'tis not

worth minding, provided the Fruit be good.

Most Plums, whether good or bad, qu't not their Stones. Damask Plums quit their Stones cassest. The Pulp in all Plums is yellow.

Of Cherries.

BOUT the middle of June Red Fruits begin to come in, and hold at least 'till the end of July; among which are reckon'd Cherries, Griots, and Biggaroes, or Heart-Cherries, to be the most principal; we may have Dwarf-Trees of them, but Standards are better. They are Fruits so well known every where, that they need no Description; none of them are so prized as the large latter Cherries, which are called Montmorancies, and next them the Biggaroes or Heart Cherries, and in the third place, the Griots, or Agriots.

The Guignes, or Gnigns, of which there are white, red, and black, or indeed early ripe, but they are

Persons of Quality: The Cherries which are call'd forward Cherries, but are not the early ones of all, or true Hastings, succeed the Guignes or Guigns; they are sair enough to the Eye, are long stalk'd, and of a sharpish and bitterish Taste, and therefore are valu'd but little, unless it be for the making of some of the first Composes, or wet Sweet-Meass.

The truly good and fair Cherries, commonly call'd preserving Cherries, are those of Montmorancy; some of them grow upon Trees that shoot out great and upright Branches, and those are the largest fort of them; but that fort of Tree bears but sew of them. They are

otherwise call'd the Cigulardy Cherry.

The right fort of good common Cherries produce small Branches, bending downwards, and bring great store of Fruit, which is very sweet and pleasant to the taste; one and the same Tree bears both long and short stalk'd ones; and it's cheisly of this sort we are to plant most Trees.

The Bigaro, or Heart-Cherry, is a Fruit both firm and crackling, longish, and almost square, but always very sweet, and very agreeoble; the Tree shoots out thick Branches that are luxuriant enough: Its Leaf

is longish.

The Griot or Agrico is a sert of Blackish Cherry, of a pretty sirm Consistence, and very sweet and excellent; it blossoms mightily, but withal is very subject to miscarry in the Blossom: It produces a thick Dwaf-Tree, with a Top compos'd of Branches, keeping close and tight together, and its Leaf is broad and blackish; none of the kinds of Merises, or common black Cherries, deserve to be admitted into an artiscial Garden, being properly Forest Trees, or Wildings, yet may they serve us at least for Stock to receive the Graffs of the choice sorts of Cherries before mention'd.

G 4

Of Apricots.

Pricots are good only for wet and dry sweet Meats, not being delicious to be eaten raw in any large quantity,

Standard Apricots

There are pretty good ones that grow upon Standard Trees, which are all tann'd and speckled with little red Spots, they are pleasanter to the Eye and Palate than those against a Wall, and of a more exquisite Taste.

Apricots against a Wall.

The Wall makes Apricoss larger, gives them an admirable Vermillion colour, and causes them to bear more certain: both forts are good for Preserving, the best of them are a little sugar'd, but usually a little doughy.

Time of Ripening, and Description.

Apricate ripen at the beginning of July, especially the hasting or early Apricat, whereof the Pulp is very white, the Leaf round and greener than the others, but no better than they.

The ordinary Apricots are more large, and their

Pulp yellow, ripe about the middle of July.

When too great a number of them knit upon the Tree, a great many must be pluckt off, and they will make excellent green Composes, or wet Sweet-Meass.

The Anjou sweet kernell'd Apricot.

In the County of Anjou there is a small Apricos with a sweet Kernel, almost like a Philbert, and accordingly the Stones are usually crack'd to eat them. It has a white Pulp, very good, and usually grows a Standard.

CHAP. IV.

Of Apples

La Reinette Grise, and La Reinette Blanch.

He two forts of Pit pins are distinguish-The Gray ed by the two Names of Gray and and White White which they bear; being in other re-Pippins. spects of an equal Goodness; good Compotes and Wet Sweet Meats may be made of them at all times. They being to be eaten Raw towards the Month of Fanuary; before which time they have a little point of Sharpness, which is somewhat disagreeable and unpleatant to some People; but when they are intirely freed from that, they contract a Smell that is much more disagreeable, when the Smell of the straw upon which they laid to Mellow, intermixes therewith. They are very Profitable, because of their being made use of almost all the year long.

La Callville d' Autumne.

The Autumn of a very Red Colour both within and without, especially the Best of them, viz.

Those that have the most agreeable Violet smell that

74 The Complete Gard'ner. Vol. I.

that renders them so considerable. These most Excellent ones have always their Pulp more deeply ting'd with Red, and are also more beautiful than the others. They keep most commonly from October, the time of their coming in, till January and February It's a most excellent Fruit to eat Raw; and no less excellent to use in Composes or Wee Sweet Meats. It sometimes grows dry and Meally, but that is not till it is very old.

Le Fenoullet, ou Pome d' Anis.

It is of a Colour not well to be expressed; 'tis Gray, over-cast with something of a Russe, coming near the Colour of the Belly of a Doe; never taking any lively Colour. It never grows very big, and feems to incline to a longish Figure. The Pulp is very fine, and the Juice much sugar'd, and Persum'd with a little smack of those Plants from whence it derives its name. It begins to be Good at the beginning of December, and keeps till February and March. Its Certainly a very pretty Apple, but is apt to wrinkle and wither, as the Cour pendu, which follows next.

Le Cour pendus

Is perfectly of the regular Figure of The short hung; an Apple, and of reasonable bigness; or, short Stalk'd of a Gray Russet Colour on one side, Apple.

and Dyed with Virmillion on the other; the Pulp is very fine, and its Juice very sweet and Pleasant. They are eaten with pleasure from December, till February and March. We must not give it time to grow wrinkled; because then it is insipid, and loses the taste. 'Tis a very pretty Apple.

La Pome d' Api

This Apple is of an extraordinary The Ladies piercing and lively Colour, It begins Apple. to be good as foon as it has no Green left, neither towards its Stalk, nor towards its Crown; which happens pretty often in the Month of December, and then it may be eaten greedily at a Chop, with its Coat all on; for among all other Apples. there is none that has so fine and delicate a Skin as this; for its scarce perceivable in the eating, and contributes much to the agreableness found in them. It lasts from December till March and April. And is wonderful good all that time without any manner of difagreeable smell; but on the contrary has a certain little touch of a most delicious Perfume. The Pulp extraordinary fine. It's a great increaser, and certainly may be commended for a very pretty Apple ; it has likewife this farther Advantage; that it never Wrinkles, nor loses its charming Colour.

La Violette.

is of a whirish, Ground Colour, a little speckled in those parts which are from the The Vio-Sur, but marked, or rather striped with len apple, a good lovely deep Red on the Sunny side. The Colour of its Pulp is very white, and very fine and delicate, having a Juice extremely sweet and sugar'd, leaving no Earthiness or Lees behind it; so that assuredly 'tis an admirable Apple, to be eaten as soon as 'tis gather'd, and continues good till Chrismas, beyond which time it will not reach.

The black Ice Apple.

This is of the fize and shape of an ordinary Pippin, of a shining dark red Colour, it keeps till April, and has always a tang of a Green tafte.

The Cosmetts.

Are a fort of Calvils, which keep till February. Their Juice very fower, Stalk long and small.

Of Vines.

The White Muscat; or, Muscattel. Also the Red and the Black Muscatt.

HE White Muscat is clear, firm, yellow, hard and crackling, Juice sweet, sugard and perfum'd; it's an excellent Fruit, its Berry round and middle fize. There is also the Red and the Black Muscat, but the White is the best.

Chasselas; or Bar sur-Aube: Three forts af them.

This is otherwise call'd the Bar-sur Aube. It's 2 very sweet Grape, produceth large Clusters, and its Grain or Berry is large and crackling; it keeps longer than any other Grape, and gives great latisfaction when all others are gone. There are Three forts the White, the Red, and the Black, whereof the White is best.

The Long Muscat.

The Long Muscat, or Pass Musque, requires more heat of the Sun to bring it to perfection, than the Mujcats before mention'd. Corinthian

Corinthian. Two forts.

The White Corinthian is a very sweet Grape, the Bunches are small and long, and its Grains or Berries small and sticking close together, and have no Stones. There is also the Red Corinthian, in shape like the former, but does not excel it in goodness.

The Bourdelais, call'd at Paris the Verjuice Grape.

Is a large white longish Grape, grows in great large Clusters, and almost never comes to Maturity; and consequently good only for Sweet Meats, or to make Verjuice with. Its Leaves are us'd much to gare nish Dishes with in October.

The Cioutar.

The Fruit very much resembles the Chasselas in Colour, Bigness, and Tast, only the Leaf of the Ciontat is dented all about the edges, like Parsly, and seems to bear more fruit than the Chasselas, but the Chasselas is better.

The early, or, forward Grape.

It's a fort of a black Morillen, and takes Colour very early, which makes it seem to be ripe long before it is. The Skin is very rough, and when tis ripe, the Grape is very sweet. It ripens commonly at the very beginning of July. It's but little worth.

There are many other Varieties of Grapes, as the Anana Grape, which ripens in the Indies, and the Pergolesse, The Passe Musque, and all other principal forts of Grapes, ripen even in the open Air in Italy; but it's not so in France, where none of them arrive to any tolerable Ripeness,

Of Figs

IGS bear twice a year viz. first in July and August, and are usually call'd Fig. Flowers; these are worth little, because they have gone through all the Cold, and all the Rain in the Spring, which spoils their delicious and excellent Taffe.

The other are ripe in September and October, which being form'd in the best Season of the Year, and nourished with a Juice well concocted, renders them far more excellent than the former.

There are several forts of Figs, but there's only Two of them that are really good, vize

Great white long Fig.

The great white long Fig is in Perfection about the end of Autumn, has an exquifite Tafte, and does not easily chap.

Great white round Fig.

The great white round Fig is a greater Bearer than the former, and almost as good, but apt to chap and gape towards the Head with wide Clefts, and thereby looseth much of its Sweetness and Persume; it's the great Rains that occasion it to crack. Ripe with the former.

Some other Varieties of Figs.

Black Fir.

It's very long, and pretty big, of a dark red Cost lour, but not quite fo red within as without; it's

Vol. I. The Complete Gard'ner. 79 very much sugar'd, but Smewhat dryer than the White ones.

Great yellow Fig.

It's a little Red and Flesh-colour'd within; bears much Fruit in Autumn, but not very delicate.

Great Violet Fig.

There are two forts, the long and the flat; but their Pulp is close, and good for little.

Green Fig.

It has a very long Stalk, a Vermillion Pulp, pretty sweet, and well sugar'd, but produceth very little Fruit.

La Medot.

It's Yellow within and without.

Black Fig.

This differs from the Black Fig before mention'd, its Pulp being red.

Small white Fig.

Its Taste is rather faint than sugar'd; 'tis call'd also the Hasting or forward Fig, because it ripens a short time before the others.

Little Berjaffotte.

It's of a dark Violet Colour, very delicate, but bears little Fruit.

Angelique

Angelique Fig.

It's of a Violet Colour, and long, but not very big, the Pulp red, and reasonably good.

CHAP. V.

How to make the best use of the Walls in every Garden.

Mong the Fruit and Kitchen-Gardens which are treated of, there are tome that are entirely inclosed on all sides with Walls, and some that are so but in part; some again that are without any at all; as for these last, they are to be pitied: But the Condition of the Gardens we have to do with, for many good reasons require to be wall'd quite about.

As for the first, they have at least three Expositions, it being not possible they should have sewer; and regularly they have four: Those which have but three, are Gardens that are Triangular, which are pretty rare: that being a cramp'd and forc'd Figure, which ought to be avoided. As to those that have

which ought to be avoided. As to those that have four Walls, they are of a square Figure, which is the commonest, as well as the fairest and most convenient.

There are likewise some that are Pentagonal and Hexagonal, which are not very disagreeable for the planting of Wall-Trees; yet are not very accountable, they being attended with many Inconveniencies; and perplex Gardners, who are thereby hindred from forming any sightly Squares in their Kitchen-Garden's. And besides, the making of Gardens into those unusual Figures, is much more chargeable, than to make them simply and plainly square; and yet, when all's

Vol. I. The Complete Gard'ner. 81

done, tho' they may have more Walls, yet they can have no more distinct Exposition than a plain Square; for let us do what we can, it's impossible to produce any more than these four, viz. East. West, North, and

Now in Terms of Gardning, we call Expositions, every Wall that enjoys the Aspect, Aspect. and kindly Reflection of the Rays of the Sun, during a certain time of the Day, in a different manner from another Wall not in the same Position: Thus we call an Eastern Exposition, a Wall that is eyed by the Sun the half of the Day; that is, from its rising 'till Noon; and that a Westerly Exposition, upon which the Sun shines the second half of the Day, which begins immediately after Noon, and continues 'cill Sun fetting. That which we call a Southern Exposition, is that which the Sun constantly shines upon longer than either of the Two former; and there are some Gardens that are so advantageously turned. that one of their Walls is almost all the Day cherithed with the Sun Beams.

Having explained the Three good Expositions, it's no hard matter to conclude, that the unhappy Northerly Exposition, is that which enjoys the Sun only during that little time in which the Southerly one has him not; the Portion of those of the North then, is to enjoy from the Equinox of March, to that of September, the earliest Rays of the Sun that appear above our Horrizon; that is to fay, to be shin'd upon betimes in the Morning, and that sometimes for an Hour or two, and sometimes for three or four, and sometimes they have a short view of the Sun towards the Evening,

but very often none at all.

It follows from thence, that there is no Wall that has not at least some little glance of the Sun once a The Sun never begins to shine upon one Wall, but he shines upon two at the same time. When he rises, he ordinarily shines at once upon the Northern Wall, and part of the Easterne; and as soon as ever the progress of his Course carries him out of sight of that of the North, he insensibly extends his Beams to that of the South, yet so, as not for a good while to quit that of the East, but shining upon both at once. In the same manner also, he leaves not off shining on the Eastern Wall, but in order to advance himself by little and little towards the Western Exposition, and to continue in the mean while his favourable Aspect to the Southerly Wall: So that those two Walls are likewise at the same time gratisted with his cherishing Rays.

Thus having explain'd what is meant in Terms of Gardening, by Expositions, any Person may easily judge of those he has in his own Garden, whether it

be wall'd quite about, or only in part.

The better the Ground is, and the higher the Wall, the greater number of Trees may be applied to them; that is, we may place them nearer to one another, and by this Means order them so, that between two which we may reserve to garnish the lower part of the Wall, there may be always one to shoot up and garnish the upper part, that so the uper and lower parts of our Fruit-Walls may be both garnished at once, and confequently yield us Fruit so much the sooner, and in greater Quantity. So on the contrary, the lower the Walls are, so much the farther the Trees are to be placed one from another, and those Distances must still be more enlarged where the Ground is very rich, than when it is but indifferently qualified.

Our Design in planting Wall-Trees, is indeed to have so much the sairer Fruit, but still more cheisly to secure the greater Store of it; but Trees do not infallibly yelld Fruit, unless it be upon seeble Branches;

and therefore we shall have no Fruit upon our Wall-Trees, unless we contrive it so, that we may shave some feeble Branches on them: And if the Tree be vigorous, as they are commonly in good Soils, they cannot produce any feeble Branches, unless they be allowed a great deal of room, to spread out to the best advantage all those that are fit to bear, because that suppoling they be planted too near one another, and the Walls not be high enough, they must necessarily be prun'd short, or else they will shoot above the Wall, and consequently will cease to be Wall-Trees; or else they will so entangle their Branches one with another, that they will make a very disagreeable Confufion. So that if then they be curb'd in that manner. if we leave them not Branches of some considerable Thickness and Length, all the young Shoots they produce will be always thick, and bear no Fruit.

As no Walls of Inclosure ought to be less than seaven or eight Foot high, so likewise it is not convenient to desire Walls in a good Exposition of above

fifteen or fixteen Foot high.

Reader, you are defired to observe, that what is material in Monsieur La Quintinye, from the end of his second Book, to the end of the Fisteenth of this Part, consisting of Pears, Apples, Peaches, Plums, Figs, Apricots, Cherries, &c. is now comprehended in the precedent Chapters of this Part; the Abridgers thinking it most convenient for good Order, and Method's sake, to place all the Fruits successively We proceed now to the sixteenth Chapter.

CHAP. XVI.

What good Conditions are required in each Fruit-Tree, to qualifie it to be chosen and preserv'd to some good place in a Fruit Garden.

UR Garden being form'd, dunged, accommodated, divided, and, in fine, ready for Planeing, and every Gentleman knowing what number of Trees he needs, according to the bigness of his Garden, and having also resolv'd upon the Choice of the Kinds, and what proportion of each kind he is to plant, with respect to the quality of his Ground, and to the several Seasons of the Year; it is now our business to chuse such stocks of Trees as are fair, and so well qualified as to deserve to be planted, because of the hopeful Promises they make us of answering our Expectations.

And here we ought to have to do with Gardners that are in Reputation, to be knowing, exact, and faithful; for otherwise we run a great Danger of being grosly deceived in the kinds of our Fruit, and especially of Peach-Trees, because they all much resemble one another, both in Leaf and Bark, excepting the Troy Peaches, the sorward or Avant Peaches, which are distinguished by some more visible differences: For which reason it is not advisable to take any Trees of suspicious or unknown Gardners, or that are of ill Repute, how cheap a Bargain soever they may offer them; such an Error as that being of two great a Consequence to be ventur'd on at what rate soever.

Tree-Stocks then are to be chosen, either whilst they are yet growing in the Nursery Gardens, or after they are pull'd up, and brought from thence: In both cases we must consider first the Figure of each Tree; Secondly, its Bigness, or Thickness; Thirdly, in

what

Vol. I. The Complete Gard'ner. 85

what manner they are fashion'd and composed; and if they be already pull'd up, we must take special netice of their Roots, and of the Bark; both of their Bodies and Branches.

CHAP XVII.

How to Choose Trees as they stand in the Nursery-Gardens.

F we chuse our Trees in the Nursery Gardens, which twere always to be wished we could; and that about the middle of September to mark out the Trees we chuse and pretend to carry off. Which cannot be always done, because of the too great distance we are fometimes from the places where the Choice Nurseries are. Yet if we can go to the places, we must only fix upon those that have shot vigorously that year, and that appear found, both in their Leaves and at the end of their young Shoots, and by their smooth and shining Bark; so that if any Trees have no Shoots of that year's growth, but what are very feeble, or perhaps have none at all; if any before the Season, or the fall of the Leaf, have all their Leaves leffer, and more starving than they should be and the extremity of their young Shoots black and mortified, or their Bark rough and wrinkled, and full of Moss; and if Pears, Apples, or Plum Trees be Canker'd, if they be Stone-Fruit, and are found to have Gum either about their Body or Roots, all these are so many Marks of those which are to reject.

As to the manner how Trees should be fashion'd; that is for all forts of Dwarfs, or Wall-Trees, it is better they should be straight, confissing only of one Stem, and one Graft, than to be compos'd of two or three Grafts, or several Branches. The new Shoots that will shoot out, round about the single bo-

H₃ dy

dy of the Tree, when top't and new planted, being more fit and plyable to be turn'd as we would have them to make a fair Tree; than if they confifted of two Sticks or Branches; because we cannot be affur'd, from what part of those old Branches, of the new-planted Tree, the new Shoots will sprout; and because commonly they grow to confuledly and interwoven one among another, that we are forc'd to cut them quite away, which is time loft, both for the Advancement of the Beauty of it, and of its producing Fruit.

These Trees ought to have good Eyes or Buds, which may promise good Branches; and especially in Peach-Trees; so that we must never take those whose Eyes are seemingly put out; because it's very rare that any iffue does proceed from fuch: Likewite if there be-Grafts or Inocculations, it will be best to take away the weakest, and to preserve that which is strongest and

best plac'd.

As for Standards, which are planted in the full open Air, they require no regular exactness in their Beauty, and therefore may be planted with some Branches about their tops, which may be shortned when they are planted.

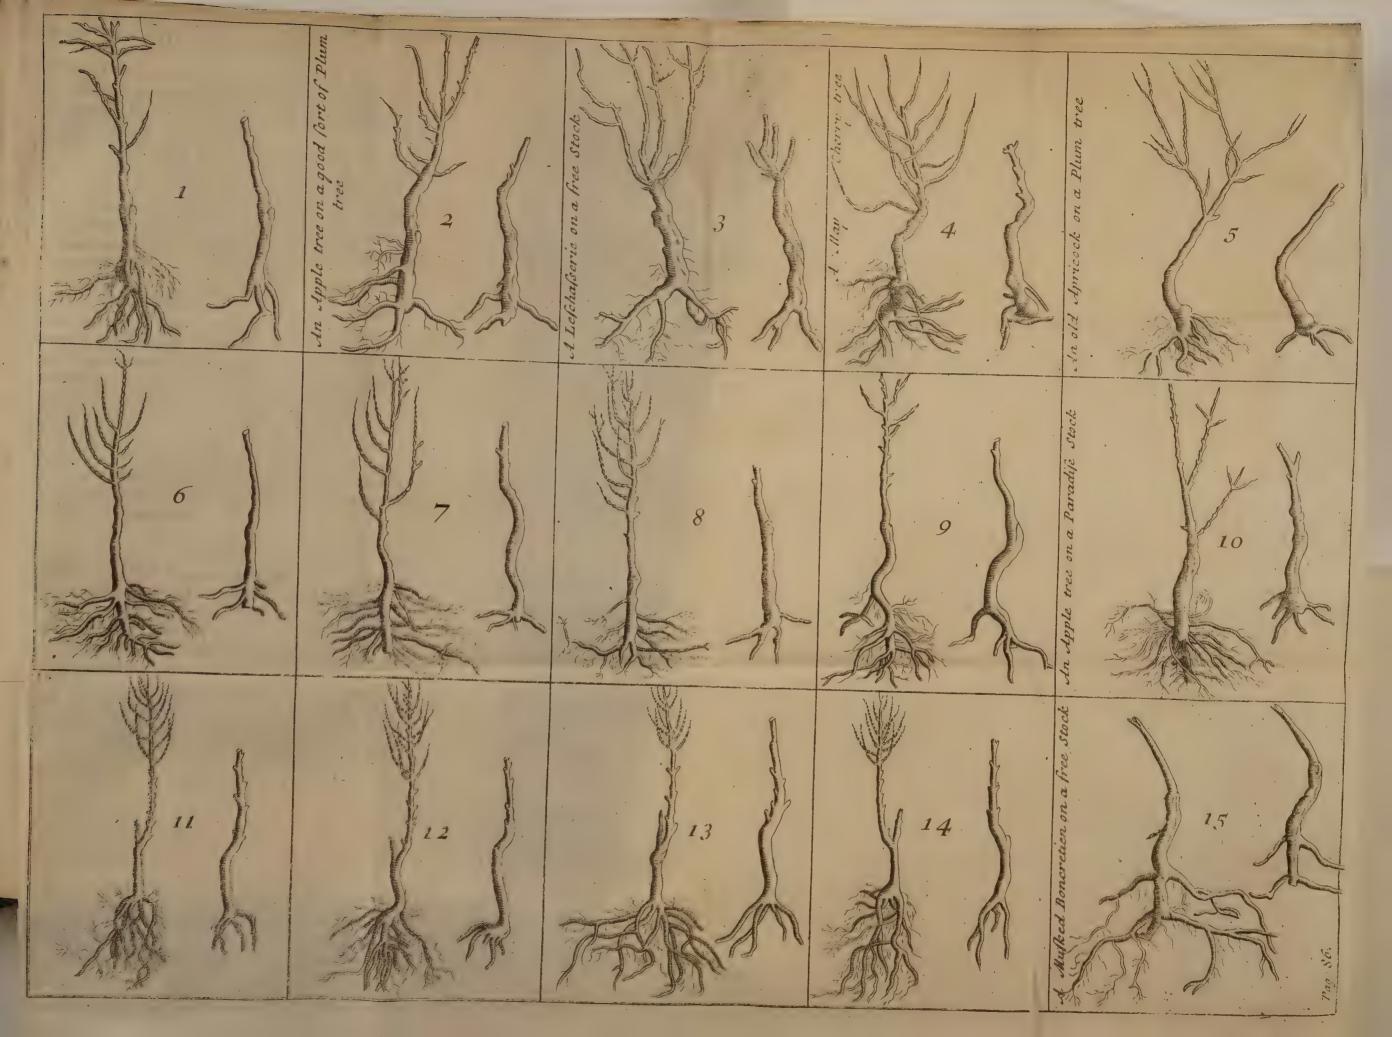

CHAP. XIX.

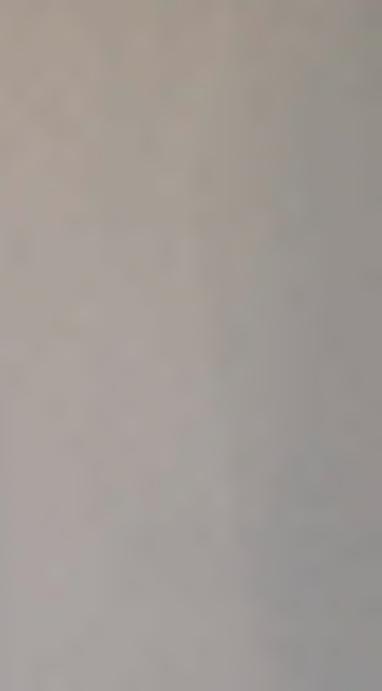

How to prepare a Tree for Planting.

Here are two things to be prepar'd in planting of a Tree, viz. The Head and the Root.

As to the Head, there is but little mystery in ordering that, either in Standard or Dwarf Trees; it being needful only to remember these two Points.

First, As we prejudice a Tree when we pluck it up, by weakning it thereby, and abating its vigour and

activity for tome time; so we must therefore disburthen its Head, proportionable to the strength and activity we take from it by recovering it to a new place,

and retrenehing some of its Roots.

Secondly, We must be mindful to leave its Body no higher than is Convenient for the use the Tree is design'd for: Some being to produce their Effect very low, as Dwarfs and Wall Trees, which must be kept pretty short; and others to produce theirs very high, as Standards, which therefore must be lest of a suitable heighth.

As to the Roots, cut of all the Fibres, as near as you can to the place from which they sprung; unless it be a Tree that is to be planted again the very moment it is pluckt up, without leaving it the least time that may be out of the Ground; otherwise the Air turns all the young Roots or Fibres black, and consequently spoils them. But this can never be done, except we pull a Tree up, and Plant it again in another place in the same Garden. And for the better preservation of it, we may take along with the Root some of its former Mould that hangs next about it; taking care in planting it, to place and spread out well that hairy or sibrous part.

As to those that have been taken up some time, the Fibres being all taken away, we shall be the better able to see the bad ones, to take them quite off; and to discern the good ones to save them, and to regulate the cutting them their exact length; and when we find the Roots of any Tree a little or ought too much dryed, they may be steeped seven hours in water before

they are planted,

In speaking of good and bad Roots, it may be thought, that the meaning of these is only such as are broken, or unbarked; rotten, or dry: But yet there is something of greater Consequence, which

H4

is

is, that every Nursery Tree shoots out sometimes either all good Roses, or bad ones, or both good ones and bad ones at the same time; which comes to pass as follows.

A Tree planted with the preparations recommended, if it takes, must Shoot forth new ones, or else it dies; all its old Roots being of no service to it: And of those new ones some are fair and thick, and some are feeble and small: but of these Roots we are only to esteem those which are fresh and new, and well plac'd.

All these young ones are to be kept short, proportionable to their length; the longest in Dwarfs, of what bigness soever it be, which is commonly not very big, never exceeding above eight or nine Inches; nor much above a foot in Standards. We may leave a greater length to the Ross of Mulberries and Almonds; because those of the first are very short, and those of the second dry and hard, and therefore will be in danger of perishing if they be cut too short.

After we have fixed the length of our biggest Rous, the length of two, three, or four Inches will serve for the lesser and seedle ones, proportionably to the bigness of each, the least always to be the shortest; for this is to be done contrary to the method of Pruning

Branches.

One fingle rank or story of Roots is enough; and two or three good Roots, when they are well placed round the foot of the Tree, are better than twenty midling ones.

CHAP. XX.

When and how to Plant Trees, when ready fitted and prepared for it

T the Season for Planting, which is commonly from the end of October to the middle of March; in order to Plant, we must always chuse dry and mild weather, without any regard to the age of the Moon; rainy weather being apt to reduce the Mould to a Mortal-like consistence, which causes it not to settle so well about the Roots, leaving some hollowness be-

tween the Earth and some parts of the Roots.

And though all these Months are equally fit for planting, so that it may seem the sooner it be done the better; yet as it is best to Plant in a light Soil presently after Michaelmas, so it is safest in a cold and moist Soil to Plant at the end of February, because the Trees in these last can do nothing all the Winter, and may more likely be spoil'd there, than be able to preserve themselves; whereas in lighter Grounds they may begin even at that very same Autumn to shoot out some small Roots, which is a great advancement to them the following Spring,

Having opened the holes, and laid every Tree to its place, we must take care to fink our Trees about halt a foot, that is, the extremity of the lowest Root of the Tree is to be but half a foot deep in the Earth; because the Ground will sink at least half a foot, and it is better to plant too high than too low. At the end of some Months the Trees will be sunk to the depth of about a foot into the Earth, which is the justest measure we can assign them in that respect. Trees plan-

ted deeper almost always dying in a few years.

We must likewise be mindful to turn their principal Roots as much as may be to the good Soil, And tho tho' all Trees design'd for Dwarfs ought to stand upright upon their seet after they are planted; yet if the Disposition of their Roots naturally incline to spread round, and require that the Tree should be a little stooping, to give that good Situation to its Roots which they ought to have, it must be allow'd.

If we are to plant Trees along by the fide of a Walk or an Alley, we must take care to avoid turning the principal Roots towards the Alley? as also in planting of Wall-Trees to have the like care in placeing the Roots; not that any of them may spend their

Vigour in vain against the Walls.

Standard Trees must be planted a little deeper than others; that is, about a full foot deep in the Ground; and whereas trampling is not good over small Trees to make them sink too deep, so it may be required to press the Ground against the sect of these Standards, to fasten them, and make them the sirmer to resist the violence of the Winds.

After the Planting of every Tree, if you have the conveniency of a Dung-hill, it will be of very good use to put a bed of three Inches thick of Dung over every Tree, and cover it over at the same time with a little Mold, to hide it from being seen, it being no handsome sight.

This bed of Dung is not so much to improve the Ground, which we suppose may be already prepar'd, as to hinder the burning heat of the Months of April, Mar, and June, from penetrating to their Roots.

But if Dung cannot be had, we may content our selves for those first dangerous Months to cover the seet of our Trees with a bed of Green Weeds, Fern, &c. hindring any thing from growing there that may shade or cloud the young Shoots; and if it be a great Drought, as if it often happens, a Pitcher of Water may be given to the Root of each Tree every sitteen days, during the three or four hot Months, making first a Circular Trench round the Tree, that

Vol. I. The Complete Gard'ner.

91

the Water may pierce quite down to the Roots of the Tree; and when the Water is all imbib'd, fill up the Trench again, as it was before, with the rest of the Ground; but if the Season proves rainy, these waterings will not be necessary.

CHAP. XXI.

How to order Trees planted for Reserves, in Ofice Cases or Baskets.

B Ecause some Trees may happen to die, and yet as far as 'tis possible it is to be desired our Plantation should be completed the very first Year, therefore it will be requisite to prepare a greater number of Trees than we have actually need of, that we may always have some as 'twere in a Body of Reserve for that purpose, as we are filling up our Plantations, to plant some supernumerary Trees of every kind in Osier Cases or Baskets; but more of Stone than of Kernel-Fruit, because the former most commonly are in greater hazard of dying than the others.

Accordingly we must chuse some good shady Place in our Garden to plant these Trees in Baskets, well ticketted, or at least set down carefully in our Book, according to the other both of their Ranks, and of the respective places allotted to them in those Ranks; that we may have recourse to them, if any Tree should

happen to dye, or languish in its place; being desirous, if it be possible, to have our Plantation finish'd and completed according to our first modelling of it.

In order to which, we should keep a leaning Poflure in the Reservatory Baskets that are design'd for the Wall, and in a streight and upright Posture in the said Baskets for these that are intended for Dwarfs; So that when we have occasion for either of them, we may the more commodiously remove and place them, Basket and all, so as the Tree may be every whit as well situated, as if it had been first planted there.

This Transporting of Reserve-Trees may be done still Midssummer; but before their Removal; we new water those Trees we design to transport, which probably will be the fairest we have, moving the Earth away neatly round about the Basket, for fear of breaking their Roots; in case they have shot any beyond the compass of their Basket. We must chuse rainy Weather to do it in, or at least mild and temperate Weather; and a time when the Sun is low, or a little after he is set, or a little before he rises: We must likewise be very careful not to shake the Tree in removeing it, for fear of loosening it, which is very pernicious and often mortal.

When in removing of these Trees we perceive any of the Roots to be struck thro? the Baskets, we must in placing it be very careful to preserve the Points of those new Roots, place them well, and support them with good Mould, cover them immediately, and ram the Earth close against the Basket, and then water the Ground plentifully round the Basket, to make the Earth next to it cleave the closer against the Basket, so as

there may remain no hollowness between.

On those Days when the Sun shines hot, we must cover the Head of the Tree with Straw Skreens, still such time as it begins to sprout, and then we may begin to take them off ar night; but this last Precaution is not necessary, but when we see any new Roots sprout out of the Baskets, or when the Tree has been shaken and looken'd. We must take great care not to expose any of the new Roots to the Air, otherwise they will presently grow black and die.

The Bignels of the Baskets must be in proportion to the Roots of the Trees, that about three Inches distance may be between the Basket and the longest

of the Roots, in order to put good Mould therein.

The Baskets for Standards must be greater than for Dwarfs, and those for Dwarfs bigger than those for Walls.

A little cost will put our Minds at ease in this respect, and for want of that we lose much Time and Pleasure too.

Let us now proceed to the Master Work of Gard'-

ning, which is Pruning.

OF

FRUIT-GARDENS,

AND

Kitchen-Gardens.

VOL. II. PART. IV.

CHAP. I.

Definition of the Pruning of Trees.

PRUNING is an Operation of Gard'ning for three three Things which are to be done yearly to Trees, from betwixt the beginning of the Month of November to the end of March.

First, to take away all those Branches that are nought, or might be prejudicial either to the Abundance or Goodness of Fruit, as also to the Beauty of the Tree.

Secondly, To preserve all those that may be of good use to those Trees. And,

Thirdly, Prudently to clip those that are found too long, and not to cut any thing off those that have not too much Length.

And all this in order to make a Tree lasting, to beautifie it, and at the same time dispose it soon to bear a great deal of fine and good Fruit.

By Branches that are nought, are meant those that are of false Wood, those that are decay'd by having vielded much Fruit, and those that are too small, or have no disposition to produce either Wood or Fruit.

By Branches that may be prejudicial either to the Beauty of the Tree, Abundance or Goodness of the Fruit; are meant, such as cause a Consusion, or shadow the Fruit, as well as those that take part of the Sap of the Tree, when it is over charg'd with Wood, compar'd to it's Vigour.

By Branches that may be of good use, are meant all those that are so well condition'd, as to be fit to contribute to the Beautiful Figure of the Tree, and in-

fallibly to produce Fruit.

By Branches that are too long, are meant such as exceed nine or ten Inches in length, and so consequently want to be shortned; such are all the thick Branches which we call Branches for Wood; and some of the small ones, which we call Branches for Fruit.

By Branches that have not too much length, are meant certain little Branches, which being of a moderate thickness, have Buds at the ends of them, or are in a disposition of having some the following Year, and yet are strong enough to bear the Fruits they are to produce without breaking.

This so material distinction in point of Branches, shall be more particularly explain'd in the Chapters

that treat of the manner of Pruning.

96 The Complete Gard'ner. Vol. II. CHAP. II, and III.

Of the Reasons, and Time of Pruning.

HE Reasons for which Pruning is us'd are two; the first and cheif is, the speedy gettting of abundance of fine and good Fruit: The second informs us that Pruning Serves to make Trees in all Seasons appear more agreeable to fight, than they would do if they were not prun'd.

The Satisfaction of this last Point depends wholly upon the well understanding, and well proportioning the Figure which a skilful hand is capable of giving to each Tree: And as to the abundance of fine and good Fruit, it depends, First, upon the knowledge the Gardner is to have of every Branch in particular, to know those that are good from those that are not.

Secondly, It depends upon the judicious Distinction which is to be made among the Branches, wholly to take out all those that are bad or useless, and eareful-

ly to preferve all the good ones.

It's very good to prune at the end of February, and at the beginning of March; tho' one may begin to prine as toon as the Leaves are fallen off the Trees, at the end of October, ar at least about the middle of November, which may be continued afterwards for the whole Winter, And having commonly three forts of Trees to prune, one too weak, the other too vigorous, and the others that are in as good case as can be destred, it will be proper to prune se me sooner, and others later; for the weaker and more languishing a Tree is, the fooner it ought to be prun'd, to eafe it of those Branches that are noisom and useless: So likewise the more vigorous à Tree is, the longer the pruning of it may be deferr'd.

But it is not advisable to stay 'till the end of Winter, 'till February or March; because that is the great-

Vol. II. The Complete Gard' ner. 97

est time of hurry, for all manner of Works relating to Gard'ning all comes at once, at the entrance of Spring, the Tillage of the whole Garden, the sowing of most Kitchen Plants, the budding of Artichoaks, the making of different Beds, the cleansing of the Walks, so that it would be a strange Consusion to have at the same time the most considerable of all Works to do: it being the only one in which no small Faults can be committed,

The Author hear speaks of extreme hard Frosts, such as have not been since the Memory of Man, and in those Seasons he prun'd his Peach Trees before the great Cold came on, without finding the least Incon-

veniency by it.

The proper times being regulated for Pruning, we

shall now proceed farther.

The fourth Chapter treats of nothing material, more than what's spoken of in the second: Therefore we proceed to the fifth.

CHAP. V.

Of the Idea of Beauty which Dwarfs require.

THE Beauty of Dwarfs consists in a low Stem, an open Head, free from thick Branches in the middle, round in it's Circumference, and equally fur-

nish'd with good Branches on the sides.

The height of the Head of these Dwars depends on the Age of the Trees, being low in those that are young and rising in all according as they grow, but not to exceed above six or seven Foot; it being better those Trees should grow in extent of Circumserence and Breadth, than to let them rise high: The pleasure of Sight, which dreads whatever limits it too much, particularly in Gardens; besides the Perfection

98 The Complete Gard'ner. Vol. II.

fecution of the Winds, which easily beats down the Fruit of high-Trees, is a Rule to fix to that Measure.

CHAP. VI.

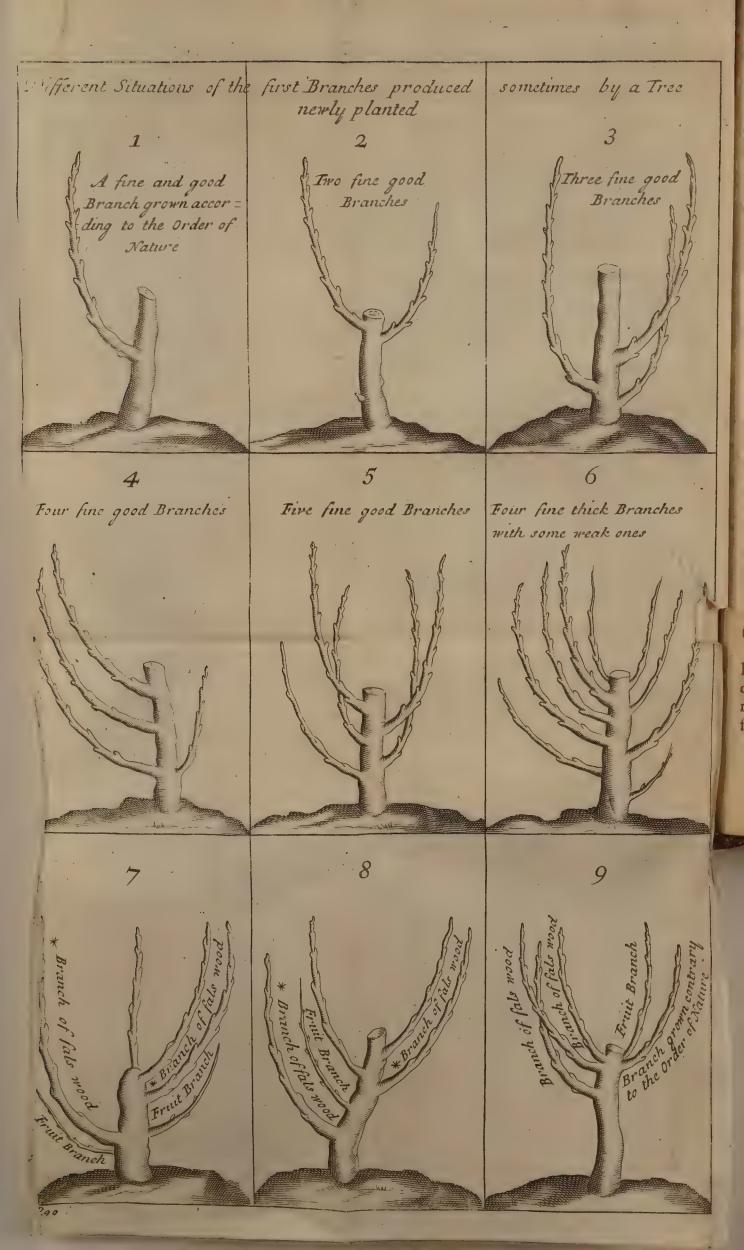

Of the Idea of Beauty which Wall-Trees require, together with the Maxims of Palisading.

A S Fulness is the greatest fault in Dwarf, so is Thinness the greatest Impersection in Wall-

But the Wall-Trees are to be full, it is not meant that they should be full of ill Branches, old, worn, or useles: So on the orther hand in desiring the Dwarfs to be open in the middle, they should not be empty, like the inside of a Glass.

In the Beauty of Wall-Trees, 'tis very difagreeable to fee their Branches crossing one another, which must be avoided as much as is possible; but to cure the defect of Thinness, it may be allowed to cross some particular great Branches which are alone the foundation of the Beauty of the Tree; but not to cross one great Branch over another, for that would occasion Barrenness; but to cross a great Branch over a small one, or a small one over a great one, since the small ones are supposed to be those for bearing Fruit; and therefore when they have yielded their Fruit, they are look'd upon but as worn out Branches; by which means the defect of Crossing may be remedied

CHAP. VII.

Of Branches in General.

D Ightly to understand Branches, Five material

things must be observ'd.

Frist, They compose a considerable part of the Tree, they sprout out of two parts of it; some shoot directly out of the main Body, which are the first, and may be call'd the Elders, or Mothers; their Number is but sew. And the other afterwards are produced by them. The Number of the last are infinite, for successively in their turns they become every one Mother Branches to many others.

Secondly, From the Body of every Branch, when the Tree is in a good case, there yearly grows new ones on the Extremities of it, more or less according to the strength or weakness of that Branch, which is call'd a Mother Branch in Relation to the new ones it pro-

duceth.

Thirdly, Observe that these new Branches grow in two different manners; the one in a Regular Order, which is the best, most common, and most frequent; the other in an Irregular Order, which is the least com-

mon, and least frequent.

That order which is most common, and best for the Production of the new Branches, when they produce more than one, is that the both the one and the other at the same time ssue from the extremities of one that is more ancient, whether Prun'd or not, they are notwithstanding regularly all of a different thickness and length.

For every one of the highest, are both thicker and longer than those that are immediately under them, drawing nearer to the body; that is when it produces more than one, for when the Mother Branches bring forth but one, the Daughter or its production at the

2.

ende

100 The Complete Gard'ner. Vol. II.

end of Summer proves as large as the Mother, and is very good; when the Mother yields two, that which is grown from the extremity which is call'd the first, or highest, is thicker and longer than that which is immediately beneath it, which is call'd the Second or lower. In the same manner, when the Mother branch produces three, four, five, &c. As the first, that is the highest, is thicker and longer than the second; so the second in the same manner exceeds the third; the third the fourth, and so by the Degrees, what ever quantity of new Branches the Mother branch may produce; as it appears by the Figures.

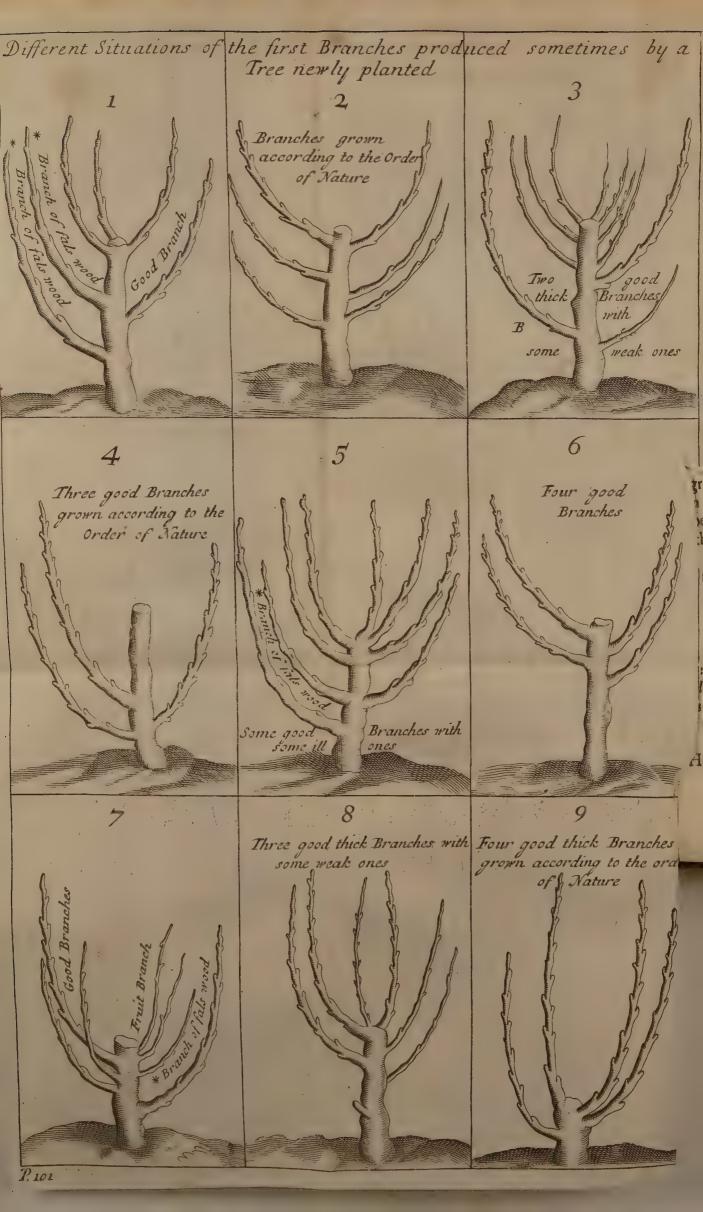

This being granted, 'tis easie to judge, that the order which is least common, and worst in the production of new Branckes, is, when the common order is inverted. So that there are Weak ones in the place where there ought to be Thick ones, and on the contrary there are Large ones where they ought to be Weak, and whereas perhaps there ought to be none; as it appears by the Figure of Branches mark'd with

a *.

Fourthly, It is requisite to know, that as that greater or smaller Number of Branches depends upon the force or weakness of the Mother-branch, it will be fit to call those Strong which are Thick, and to call those Weak that are Small.

Fifthly, This is the most Material point; that among all the Branches, whether strong or weak, there are some which have the real Character of Good, of which a great many must be Preserv'd; there are likewise some which have the real Character of Good, of which a great many must be Preserv'd; there are likewise some which have the real Character of bad ones, most of which ought to be expell'd. Let us now observe how to distinguish the one certainly from the other.

CHAP. VIII.

To know the difference of good and ill Branches.

TH E mark of Good Branches requires that the Eyes in the whole extent should be thick, well fed and very close one to another; whereas the mark of the bad ones, is, that in the lower part of the Branches their Eyes are flat, ill fed, and hardly form'd, and very distant the one from the other; as you will see by the Figure A B in which the ill ones are marked *

There are likewise small weak Branches, which are term'd as bad ones, which are sometimes so excessive weak, that like taples Branches they are incapable of bearing Fruit, or at least of nourishing and sustaining the weight of their Fruit; they must be wholly taken off our Fruit-Trees, and especially from the Dwarfs; for which Branches there is no occasion, for to do well

we must suffer nothing there that is not Good.

The good weak Branches are those, which being well plac'd, and of a mean thickness and length, are proper and certain Instruments to produce speedily, beautiful, and good Fruit; provided the Frosts spoil nothing, either while they are in Blossom, or soon after they are knit. For such Branches seldom fail of producing Blossom-buds, and cannot serve to any other end but yielding Fruit, unless they happen to have certain over-flowings of Sap, to thicken them in an extraordinary manner, and convert them into Branches for wood; which happens sometimes in all manner of Trees, particularly to fuch as have been ill prun'd.

The good strong Branches, of which the principal ule is, first to begin, and then to continue to give the Trees a proper Figure, are particularly imploy'd in producing yearly on their extremities other good

Vol. II. The Complete Gard'ner. 102

new Branches; some strong, and others weak; as

appears by the Figure As.

To that end it is very material to preserve the good weak ones for Fruit; it is likewise very necessary to manage prudently the strong ones; to which purpose it is requisive to preserve on the extremities of every old Branch, some of those new strong ones that are grown there; but that commonly extends to those a small number, as to one only; but sometimes the Mother Branch being extremely vigorous it may extend to two or three.

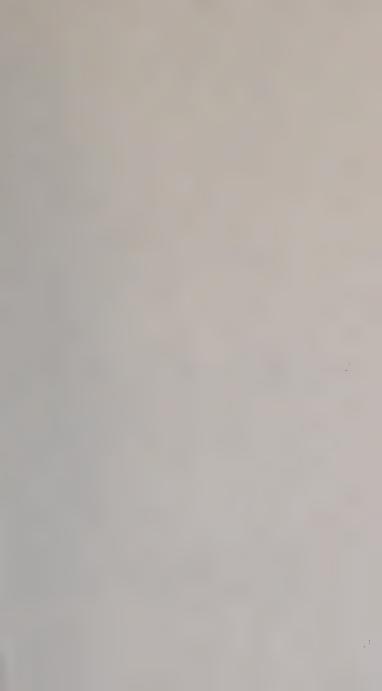

There is chiefly a great deal of Skill requir'd to take away intirely all the useless Branches, whether it be because they are worn or spen, or because they have on good qualifications: And the same concerning that those are to be preserved, to know how to regulate their length proportionable to their force, and vigour of the whole Tree; so that asterwards, every one of them may be able to produce on its extremity, just as many good Branches as are necessary either for the Fruir, or for the perfecting the beauty of the Tree, or for preserving it when it is establish: And this is what we call Pruning.

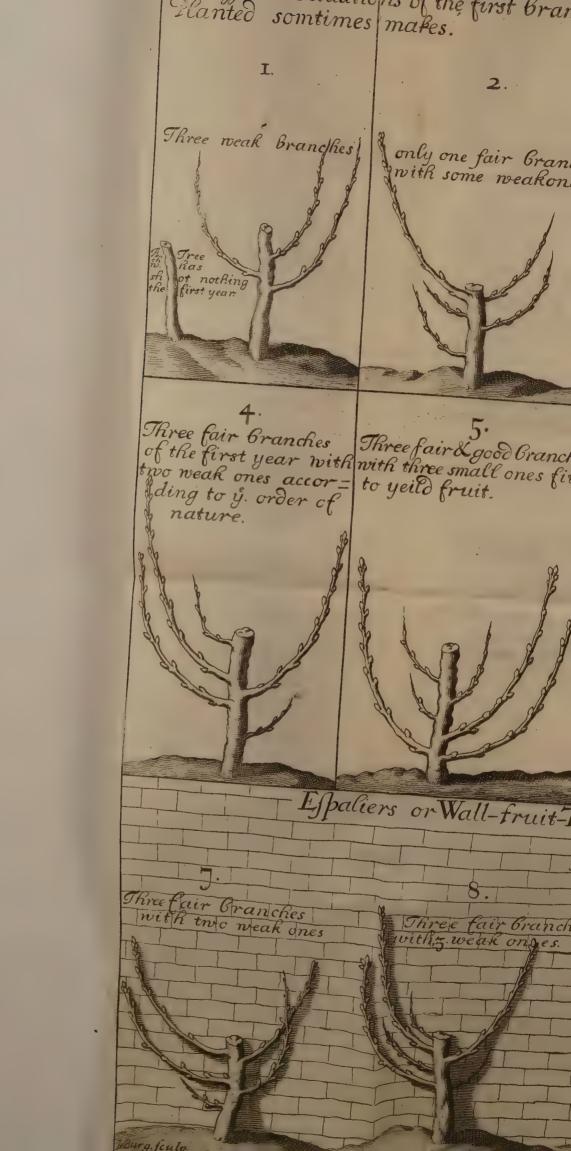

CHA.P. IX.

Of the explanation of the Words Strong and Strength, Weak and Weakness.

In speaking of strong Branches and strong Roots, are meant those that are thick; and likewite speaking of weak Branches, are meant those that are small. Moreover in speaking of a strong Tree, is meant a vigorous Tree; and in speaking of a weak Tree, is meant a languishing Tree, that is, a Tree that yields but very few Shoots, and for the most part are all small.

The

103 The Complete Gard'ner. Vol. II.

The Tenth Chapter is only of the Tools that are necessary for Pruning, and the manner of using them; and therefore may be omitted.

CHAP. XI.

Of the manner of pruning Trees, in the first Tear of their being Planted

Fruit-Tree, of what kind soever, Pear, Apple, Plum, Peach, &c. which seem'd to promise all the good Qualifications requir'd in order to be planted, and has been planted with all the Skill and Consideration which we have heretofore explain'd; this Fruit-Tree, from the Month of March, until the Months of September and October following, will necessarily perform one of these four things: Either it will not shoot at all, or little, or it will shoot reasonably, that is, one sine Branch or else it will shoot much, that is, two or three sine Branches, and perhaps more, as it appears by the Figures. We must exactly explain what is to be done in these four particulars.

CHAP. XII, XIII, XIV, XV.

Of the pruning of a Tree that has planted one Tear.

be dead, tho it does not seem to be so, by reason of some Greenness which discovers it self in cutting with the Knife; for it may seem alive at the Head, and yet be dead at the Root; however part of the Head may be dead, and the Root living; which is the principle of Life; but when it is perfectly dead,

104 The Complete Gard'ner. Vol. II

there appears a Dryness or Blackness about the Graff. Such a Tree must be removed when you find it to be dead, and another put in its Room, at the first shower of Rain, provided it be not after the Month of May, or beginning of June, after which time it will not be safe to plane, 'till the return of the Season. For this design you should have Trees always in Baskets. In the mean time let us examine how this Tree happen'd to dye, that we may prevent it for the suture.

If by violent Frosts, to cover the Foot in the Winter, as is heretofore explain'd in the Treatise of Plan-

tations.

If by Heat in Summer, to cover it with short Grass, green Weeds, &c.

If for want of Water, the new one must be well

water'd.

If for want of good Mould, put the fresh Mould there. If by being shaken or loosen d at the first sprouting, by waggish People, to set a Fence about it.

If by being planted too low in mailt Ground, plant

the other higher, and raise the Ground to it.

If from being shaded with large Trees, or by their Roses exhausting all the goodness of the Earth, these large Trees must be removed; and the worn out Earth taken away and fresh cur in, without thinking to better it with Dung.

1. If Moles have shaken them, or Worms have gnawn

them, they must be look'd for, and destroyed.

If the Stem appears to be green, and the Root still alive, there may be some hopes, but not to recompence our Culture; therefore it may be order'd as a dead Tree, it being a great hazard whether ever it will complete our desire.

2.dly. If this Tree shoots weak, small, and yellowish Branches, and sometimes accompanied with some Frust-buds; and after have examined the Roots find some

Vol. II. The Complete Gard'ner. 105

of them defective, it's no more valuable than the former.

3 dly. If it has produced one fine Branch, sufficiently thick, attended with some weak ones, we are to consider three things.

Whether it has shot from the extremity of the Stem,

from the middle, or from the lower part.

If from the extremity, shorten the Stem of that Tree an Inch or two.

Thus in losing the Pleasure of a Year, we avoid the diffatisfaction of having a Tree too high in the Stem, and consequently it affords us a fine Figure.

But if this fine Branch has shot from the middle of the Stem, cut the Stem to that Branch, and shorten that Branch to sour or five Eyes; it being certain 'twill produce in the second Year, at least two sine Branches opposite to each other; but this care must be taken to nail that Branch upright.

If this Branch has shot from the lower part of the Stem, it's very well plac'd, provided care be taken to keep it upright, which if it is not, the Tree grows

awry, and never makes a beautiful Figure.

This Branch being cut at the same length which the Seem of the Tree was left at, undoubtedly it will produce fine Branches, towards the attaining of a beautiful Figure.

4thly. When this Tree has produced two fine Branches, or three or four, or more, with some weak ones among them; it engages us to these Considerations.

1. To know whether that number of Branches be produc'd to our likeing; that is, whether they grow round about some part of the Stem, whether at the

top, in the middle, or in the lower part.

2. To know whether all those Branches are grown on one side, all above one another; or whether in degrees, at a great distance one from another, tho round about the Stem; or if they are all grown from

oné

Vol. II. The Complete Gard'ner. 106

one and the same Eye, and likewise whether it be on

the top, middle, or lower part of the Stem.

Lastly. To know whether all those Branches of themselves are dispos'd to open and spread, or all of them to keep close together in a confused manner.

These are almost all the different ways in which the first Shoots of every Treee new planted do form.

themselves, when it strikes Root.

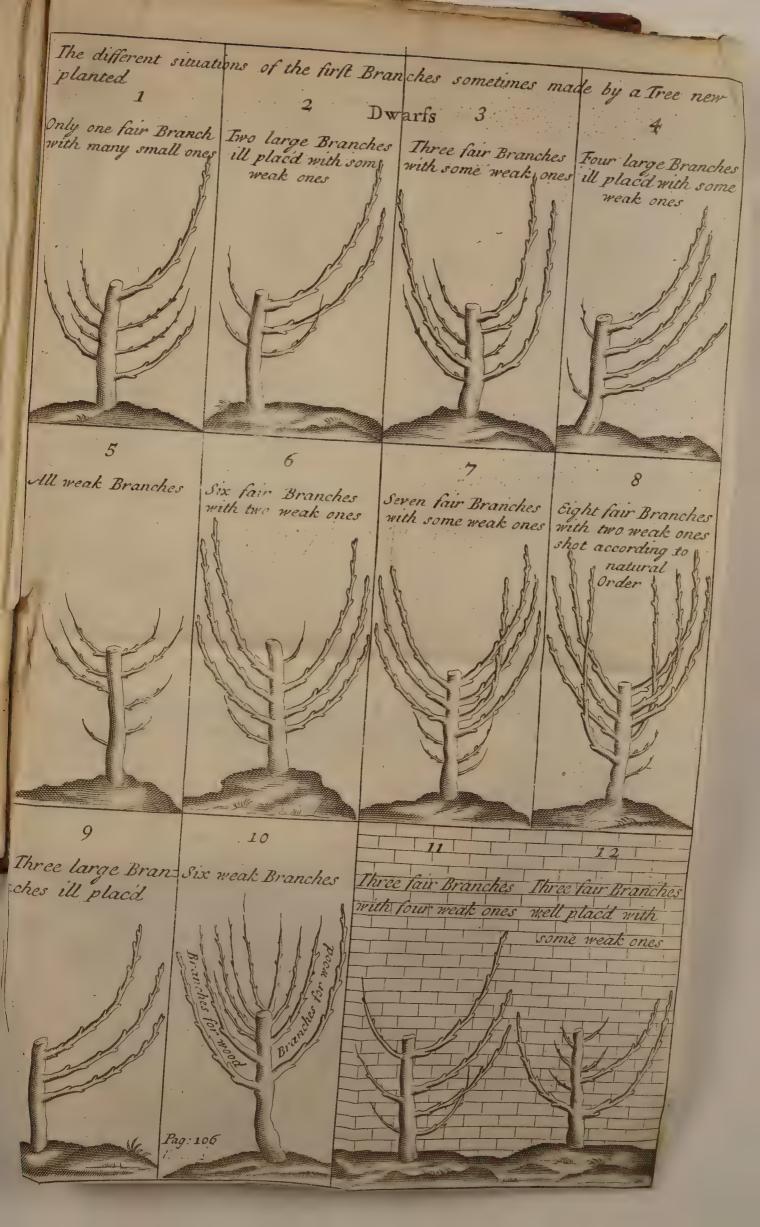

In defiring of fine and good Trees, the great Branches are only to be preferv'd in this respect? as the only ones that can ferve for the first Foundation, in case they be well plac'd

CHAP. XVI.

Of the first pruning of a Tree that has produc'd two fine Branches, and both well plac'd.

THEN a Tree new planted has vigorously produc'd more than one fine Branch, with fome weak ones among them? if it has on the top of the Stem two almost equally strong, and well plac'd. one on one fide, and another on the other, nothing can hardly be defired better? the only thing is to fhorten them all equally within the compass of five or fix Inches in length: But above all, you must take care that the two last Eyes of the extremity of each of these Branches so shortned, look on the right and on the left, upon the two bare fides, to the end that each of them producing at least two new ones, those four may be so well plac'd that they may be all preferv'd: And in order to that, If it be a Dwarf, they must all contribute to form the thin round which we desire; and if it be a Wall tree, to form the flat, and full round, which we likewise design.

It would be ill Pruning, if these two last Eyes looks either on the infide of the Dwarf to fill it up, or on

one the felv to the their ches

Of

cafe

fom of the can there of the care of the care four ferv'.

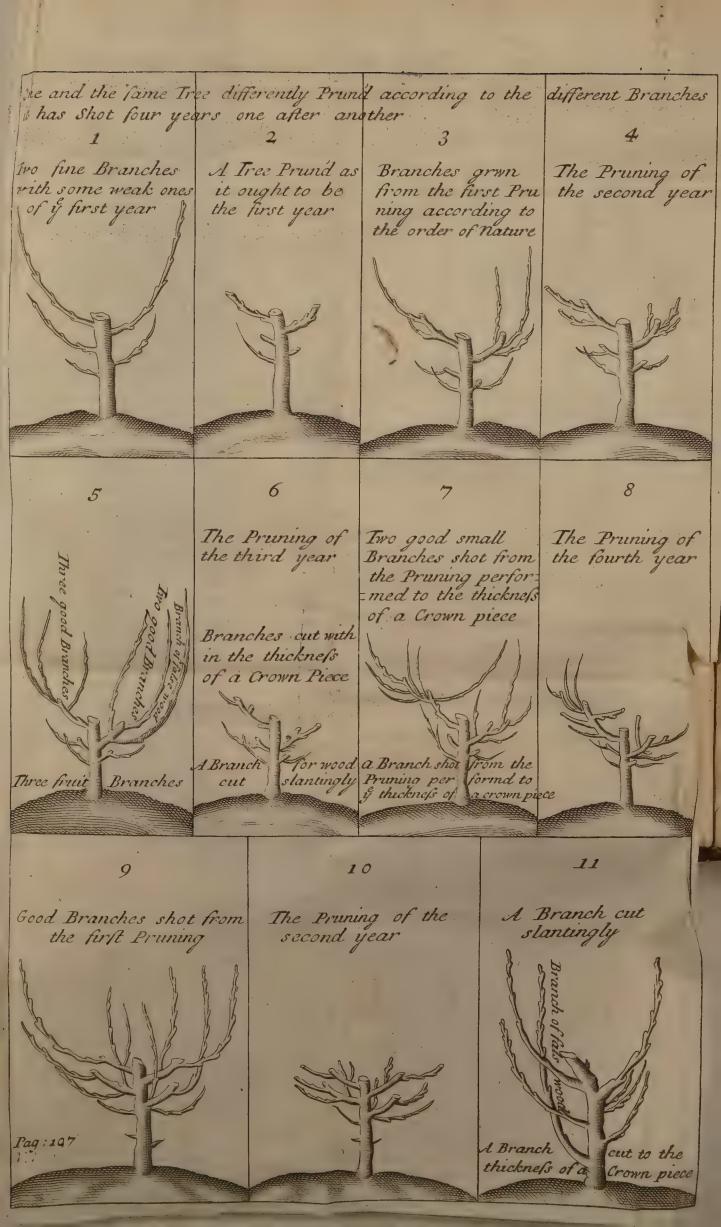

must all contribute to form the thin round which we defire; and if it be a Wall tree, to form the flat, and full round, which we likewise design.

It would be ill Pruning, if these two last Eyes looks either on the inside of the Dwarf to fill it up, or on

13 IÈ e if h 0=

or ne ite

at the bottom of the oppointe fide, you must preferve but one, the fittest to begin a fine Figure, cutting off the

107 The Complete Gard'ner. Vol. II:

the outside to open it too much, it being requisite well to establish the first Beauty of the figure of that Tree, which is to open in a round equally garnish'd: So likewise in Wall-Trees the pruning would not be well person'd, unless it were order'd so that the two Eyes on the extremities of the two Branches that are to be shortned, should shoot upon opposite sides the new Branches they are able to produce; for it's necessary that those very Branches should have of themselves, and without the least Violence, a natural disposition to place themselves well upon those parts of the Wall that we would cover.

If one of those two Branches has any advantage in Thickness over the other, so that in probability the one may produce two other thick ones, while the other can yield but one, care must be taken, that as well the two of the thickest, as the single one of that which is not so thick, may come forth so, that all three together may be preserved, as sit and necessary for the composing of the beautiful Figure; otherwise if there should be a necessity of removing some, being ill-savouredly grown, it would be a lose,

If a Fruit branch should chance to be join'd with

the two Wood branches, it may be preferv'd.

CHAP. XVII.

Of the first pruning af a Tree that has only produc'd two Branches, loth beautiful and thick, yet both ill plac'd.

If one of these fine Branches which this Tree has produc'd be considerably lower than the other, or perhaps both on one side, or it may be one on one side on the top of the Extremity, and the other quite at the bottom of the opposite side, you must preserve but one, the sittest to begin a fine Figure, cutting off

the

108 The Complete Gardiner. Vol. II.

the other so close that it may never be able to produce any thick ones in the same place; it being certain, that if both were preserved, it could never form a Tree of any agreeable Figure.

If the lower Branch be equally good, or better than that above, it will be most proper to leave the lower-most, being sittest to contribute to the Beauty of the Tree.

CHAP. XVIII.

Of a Tree which has produc'd three or four fine well plac'd Branches, or else three or four ill ones, and those all on the extremity, or a little beneath it.

I F they are on the Extremity of the Stem, and in a proper place at first to form a fine Tree, they must be prun'd with all the same regards we have explain'd, for the Fruning of the two first which were by themfelves. If these three or four Branches be all of an equal thickness, they must be all us'd alike. If one or two of them be somewhat less in thickness, but still fit to be Wood-branches, or at least half wood, and capable of contributing to the Figure, those must only be prun'd with a prospect of getting one only new Branch from them, taking care to have it on that fide that shall be found most empty; and to that end they must be shortned to an Eye that looks on that side, and care must be taken that the two last Eyes of the others which are stronger, may look towards the two oppofite sides, in order to begin to fill them up the more.

If those three or four fine Branches shoot out a little below the Extremity, 'tis but shortning the Stem to

them.

Vol. II. The Complete Gard'ner. 109

When the Branches that are produc'd are most of them ill ones, and cannot all conduce towards the forming a fine Tree, nor cannot all be preserved, examine whether among the three or four, there are not at least two pretty well scituated, the one on one side, and the other on the other, and whether they are not too far distant to frame some Foundation for your Figure, and that being so, these may very well answer the cutting of the others; the two that are preserved, must be Prun'd with the same regard heretofore explain'd for the Pruning of the two sine Branches.

Care must be taken, that those two being Prun'd, may be found afterwards of an equal heighth, though of a different length, to the end that those that may

shoose from them may begin our Figure happily.

Good weak Branches must be carefully preserved for Fruit, only shortning them a little on the extremity, when they appear too weak for their length, not failling to take away all the sapless Branches.

CHAP. XIX:

Of the Pruning of Trees that have produced the number of five, fix, or seven fine Branches.

IF our Tree has produced the number of five, or fix, or seven fine Branches, or more, it will be sufficient to preserve three or four of those that a skilful Gard'ner shall think sit, both by their scituation and strength, to be sittest for our Design; this being to, we must wholly cut off all the others, if they happen to be higher than those that are preserv'd, especially if they be thick, for if they are weak, that is sit for Fruit-branches, they must be preserv'd until they have perform'd what they are capable of doing.

Ħ

110 The Complete Gard'ner. Vol. II.

If among the thick ones there chance to be a great many small ones, preserve two or three of those that are best plac'd, breaking off the extremity of the longest a little, and not medling with those that are naturally short; and consequently you must take away all those that may cause a contusion.

"The twentieth Chapter, tho'it be of the second Years Pruning, is much to the same effect of that of the fast, which is fully treated on in the pre-

ceding Chapter.

CHAP. XXI.

Of the second Pruning of a Tree, that on the first Tear had produced two fine Branches for Wood

Here is little to be inserted in this Chapter, only that a Tree, of the first Years Planting, having produced two thick Branches for Wood, and one or two small ones for Fruit; if on the second Year, the Sap has alter'd its Course from the thick Branches to the small ones, then the small ones become Wood Branches, by the unexpected Sap they received.

In this case, the Pruductions of these Branches must, be cut quite off into the Mother-Branch, which will undoubtedly, the second Year, conduce to a beautiful Figure. The Production of those thick Branches, that shot the first, being us'd as Fruit-Branches, by reason of the less abundance of Sap they receiv'd than what

was promis'd.

"The twenty second Chapter mentions nothing material to be inserted.

CHAP. XXIII.

Of the second Pruning of a Tree, which had produced the first Year four fine Branches of Wood, or more.

four fine Branches, or more, 'tis certain it has a great deal more Vigour than any of the rest we have mention'd; therefore it's necessary sometimes to preserve some Branches upon it, which at that time are no ways conducing to the Figure of the Tree, but to serve for a time to consume part of the Sap, which might be prejudicial to the Branches that are to yield Fruit. These superstuous Branches may be lest long, and pruned without Consequence, since they are to be wholly taken away, as soon as the Tree is formed, and produces a reasonable quantity of Fruit.

As for those that are essential to the Beauty of the Tree, prune them all a little longer than those of the preceding Trees, that is about two or three Eyes at most, as well to avoid Consusion, as to make an Advantage of the Vigour of such a Tree, which, without such a Precausion, would not yield Fruit in a long time; because the great abundance of Sap might convert into Branches all the Eyes that should have turn'd into Fruit buds, had their nourishment been

more moderate.

Such a Tree, at the end of the second Year, appears in a manner quite form'd, by means of all the new Branches, that every one of the old ones, being Prun'd, have produc'd on their extremities; and among the new ones, care must be taken to chuse those that conduce to the Beauty of the Figure, to Prune them again partly of the same length as those which had been Prun'd for the first time; from which they proceed,

endeavouring to distinguish whether the Branch, that has been prun'd, may at least produce two, in order to preserve them both, if they are fit for our Design; or if one must be quite taken away, let it commonly be the highest, for the lowest being preserv'd, is fittest for the Form, or to preserve the Beauty we look for. and by that means not only the place that is cut shall be quickly covered again, but besides it will make no Wound upon the Branches that shall be preserved, and confequently the Tree will be thereby much handfomer and founder.

But if the Vigour of that Tree be observed to continue, as it is very common, and even to augment vifibly, in such a case consustion is to be fear'd, either in the Heart of a Dwarf, or in respect to a Wall-Tree, of what kind foever, as Pears, Apples, Plums, Peaches, Cherries, &c. Therefore that tecond Pruning must be perform'd yet a little longer than the first, particularly if the Tree inclines to be close, and that length must be aboue a large Foot, or a little more, to employ that abundance of Sap which we judge must not be restrain'd, nor contain'd in a small space.

When from the second Pruning other good Branches shall be grown, which shall begin to open the Dwarf reasonably well, or to fill sufficiently our Wall-Tree, especially the Tree beginning to yeild Fruit, then we must return to our ordinary way of Pruning, of six or feven Inches upon the most vigorous Branches, and

four or five upon the moderate ones.

This great fury seldom fails of diminishing at the end of the first five or fix Years, if the Tree has been well govern'd, and then all those little Bronches which we have endeavour'd to procure in a great number at the bottom, and have afterwards preferv'd with care, begin to give us an ample Recompence for all our Pains; and pretty often on such Occasions we come to Prime over again, here and there; some of the old

Branches.

Vol. II. The Complete Gard'ner. 113

Branches which the great vigour of the Tree had oblig'd us to leave of an extraordinary length, aiming still at extending, by way of overture, on the fides, there to employ usefully the vigour of that Tree, and

to preserve its agreeable Figure.

In those vigorous Trees, we must leave upon them without any use, some Branches, cut Stump-wise, and even some thick ones, the of falle Wood, in which, for some Years space, that surious Sap, of which we have too much, may lose it self in vain, which otherwife might disorder some of our principal Parts, and even, if upon those forts of Trees any Branches of talse Wood be found, in a place where they may ferve towards the Figure of the Tree, they must be preserv'd and us'd as such ; being certain, that as they will take up the greatest abundance of the Sap, the good Branches that have produc'd these false ones will receive less, and configuently will bear Fruit the sooner; these falle Branches, in the mean time, performing the fame effect, as to the Figure, as the good ones could have done:

Such Branches may likewife be left wherever the Overture of the Tree shall not be prejudiced by them, from whence the Tree, bearing Fruit, they may, at pleasure, be taken away without any prejudice to the Figure, provided, always, they cause not the least confusion; that being the greatest harm that can happen to a vigorous Tree. To moderate the great fury of fuch a Tree, and to make it bear the sooner, two things are required besides the Overture.

1st. The length and multitude of good weak Branches, when they are placed so as to cause no Confusion.

2dly. A considerable number of out-lets upon the thick Branches, thro' which that abundance of Sup may perform its effect.

If some Branches prun'd the preceeding Year, have produc'd three or four; all pretty thick ones, you K need

114 The Complete Gard'ner. Vol. II.

need not cut them short, or retrench them, so that having one or two of the best plac'd, preserve one or two of the others for the *Pruning* of the next Year, and leave them reasonably long; besides if you preserve the lowest, cut the highest Stump wise, and when you preserve the highest, leave under them, either upon the outside, or upon the sides, one or two Stumps of the thick Branches, form'd like the Hook of a Vine, each about two Inches in length.

There happens in those Stumps, or Hooks, a discharge of Sap which produces some Branches, either for Fruit, when they are weak, or to become, in time, fit Branches for the Figure, when they are strong.

The best way is to take away the highest Branches, and preserve the lowest for the Figure, being one of the Advantages we reap by spreading the Tree with ease to the bottom of the Wall, which cannot so well be done in taking away the lowest, and preserving the highest.

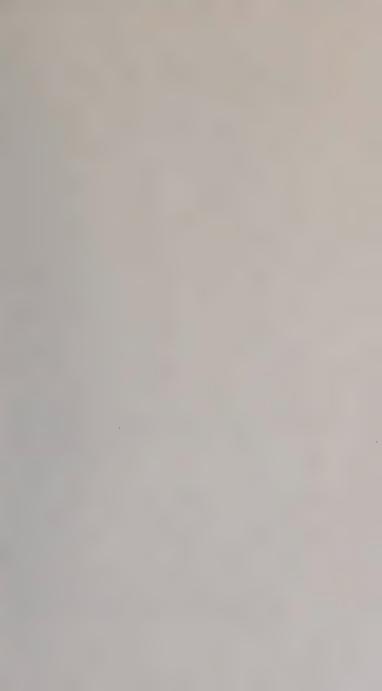

CHAP. XXIV

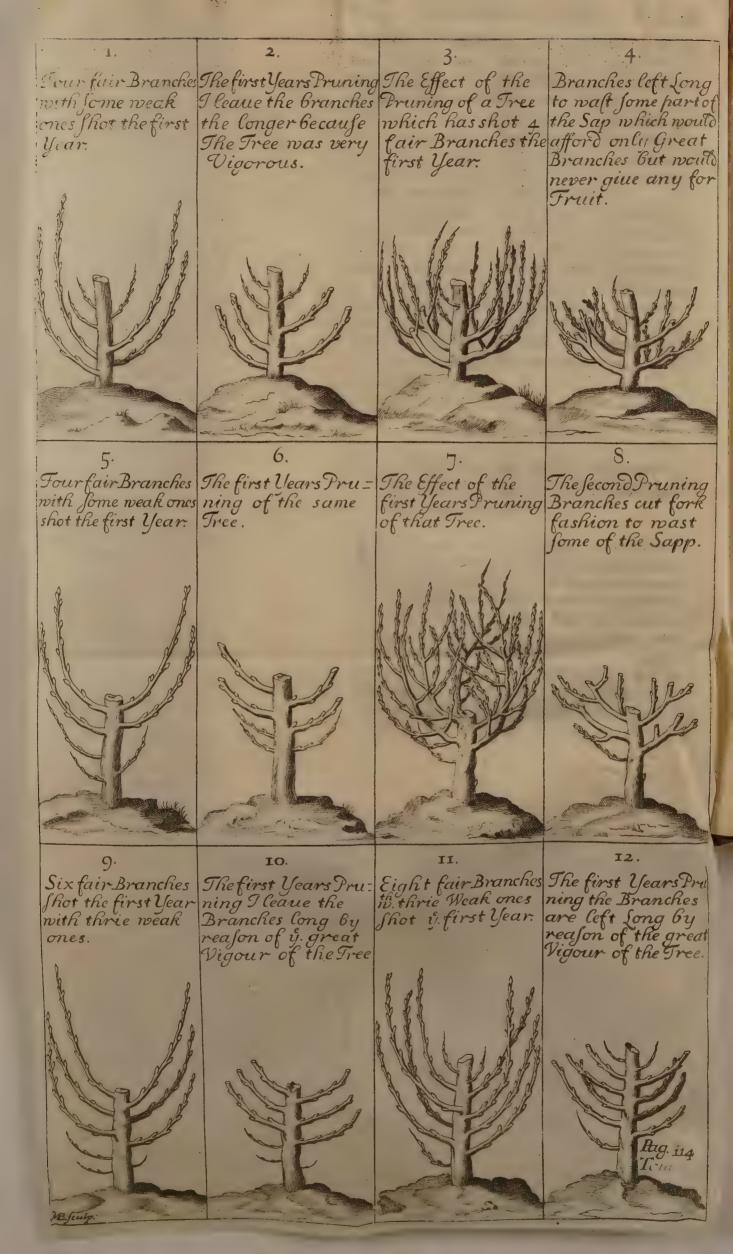

Of the Pruning that must be perform'd the third Tear npon all sorts of Trees Planted within four Tears.

which we have first of all propos'd to our selves, either in a Dwarf or Wall Trees, and to proportion the burthen of the Head to the vigour of the Roos, in leaving more and longer Branches on a vigorous Tree, and less and shorter on that which appears weak.

And whereas many old Branches must be carefully preserv'd on a vigorous Tree, (especially for Fruit) provided there be no Consustantian on the contrary, you must case a weak Tree of the burthen of the old Branches, as

wel

well those that are for Wood, as those that are for Fruit. and cut them short, in order to make it shoot new ones; but if not able to produce the young Shoots with vigour, then it must be pulled up, and a better put in its room, after having taken away all the old Earth, which may be judged to be either Ill or worn out, and putting new in its room.

In Pruning, provision must be made for those Branches that may proceed from those which you are Pruning, in order to prepare some that may be proper for the Figure, with this affurance, that when a high Branch is taken down over a lower, this being strengthened by all the nourishment that would have gone to the highest, which has been taken away, this low Branch will produce more Branches than it should have done, had it receiv'd no reinforcement.

It feldom happens that all the Trees of the same Garden, tho' order'd alike, prove equally vigorous, for Trees are subject to an infinite number of Accidents. that can neither be foreseen nor avoided; but it is certain, that all the Trees of a Garden may be form'd adgreeably in their Figure, which is one of the principal

things to which the Gara'ner is oblig'd.

Here the Author advises every body not to be obflinate in preserving Pear Trees, which yearly, towards the end of the Summer, grow extreme Yellow, without having produced fine Shoots, nor those of which

the extremities of the Branches die every Year.

They are commonly Trees grafted upon Quince Stocks, of which some of the principal Roots are dead or rotten; they are Trees that produce but small Roots at the upper part of the Foot, and confequently Roots that are expos'd to the Injuries of the Air and the Spade.

The same thing may be said of the Peach Tree, that appears the first Years to gather Gum at the greatest part of their Eyes, and of those that are extremely at-

K 2 tack'd

116 The Complete Gard'ner. Vol. II.

tack'd with certain little Fleasand Pilmires; such Peach-Trees have certainly some rotten Roots, and will never do well.

Those Trees that shoot on all sides an infinite number of little, weak, sapless Branches, with some thick ones here and there, both the one and the other for the most part, of salle Wood, in which case, a great deal of time may be lost upon ill grounded hopes. To that it will be best to remove them as soon as may be; and when they are not too old, or the Roots spoil'd, venture to plant them again, in some other place, in good Ground, after having cleansed them of all their rottenness and canker, in order to see if they will come to any thing, to make use of them, essewhere; which happens sometimes with Pear Trees, but very seldom with Stone Fruit, especially Peach Trees, still putting better in the room of them, with all the conditions heretofore explain'd.

CHAP. XXV.

Of the first Pruning of Trees that have been Planted with many Branches.

HO' it is not advisable to Plant little Trees with many Branches, yet if any have done so, obferve these Rules. First, cut off what ever may cause a consusion, or is not proper for the Figure. And Secondly, those Branches we preserve upon them, leave them at six or seven Inches in length, and observe the foregoing Rules in Pruning.

Trees planted with many Branches upon them, are not so easily turn'd to a fine Figure, as young ones chose out of the Nursery; they generally produce their young Shoess disorderly, and consequently must be often cut and wounded, before what's desired can be effected.

Vol. II. The Complete Gardner. 117

And when Trees have been Planted with a great many more and longer Branches than should have been, and there appears no manner of disposition towards the Figure we ought to wish for, we must immediately reduce them.

In a great Plantation where other Trees are dead, and supposing the Ground to be good, and other good Mould put into the hole; in such a case, Trees with some Branches may very well be Planted, especially those which are difficult to fructifie.

C'HAP. XXVI.

Of the Pruning of Tall Standards, or highbodied Trees,

Igh Standards planted against Walls do all require the same precaution as the low ones, but those that are planted in the open Air, they need only be touched once or twice in the beginnings; that is in the three or four first Years, in order to remove some Branches from the middle, or to shorten a side Branch which grows too high, or too long, or bring in another nearer, that extends beyond his bounds and refer the rest to Nature.

"Our Author speaks very rightly of high Standards,
"not being Prun'd with all the Circumstances us'd in
"lower Dwarfs or Walls; yet so far must be observed,
yearly to cut and clear cut all such Branches which
grow in the middle of the Tree, together with all the
canker'd Shoots, otherwise being overburthen'd 'twill
cause a confusion, and too much a thickness of Wood
will deprive the Fruit of the Sun it ought to have.

CHAP. XXVII.

Of the first Conduct of Graffs in Slits made and multiplyed upon old Trees, in place, either Dwarfs or Wall.

Sometimes for change of Fruit, old Trees are graffed, of one Head, two, three or more, and some of them with one Graff or more ineach Head, in pruning these observe the former directions; and where there are many Shoots, cut off such as grow inward, or are too thick: Both for number and length respect must be had to the quantity of Sap that is to supply, so as not to check it too much, tho afterwards you cut off or shorten some of them, always taking care to do it so as the Figure you design may be best accomplisht, and the lower part kept thick enough,

CHAP. XXVIII.

Of what is to be done in cases not foreseen, and pretty common to all sorts of Trees, evento those that have been manag'd according to all the Rules of Art.

HAT has been already said, may give a sufficient knowledge in this matter, yet Nature answers not all our Intentions. Times and Seasons, or Grounds, and the different temper of Trees, and the particular Kinds of Fruse, which may produce Inconveniencies which we could not foresee. For after we have prun'd and manag'd our Trees, according to all the Rules of Art and Discretion, yet Nature will produce disorderly and confus'd Branches, which when they come to pass ought to be remedied.

Stone

Vol. II. The Complete Gard'ner. 119

Stone Fruit, especially Peaches and Apricots greatly require a second, and sometimes a third Pruning, besides what's done at the end of Winter; those last Prunings must be perform'd towards the middle of May, when the Fruit is either knit or blasted; at which time they are not only advantagious, but very necessary: At the same time you must likewise Trim the Buds and useless Branches of some others, which is no less necessary than those kinds of Prunings.

These last operations, viz. The second and third Prunings of Stone Fruit, and the Trimming of the Buds and useless Branches of all manner of Trees, are necessary both to strengthen certain Branches which may be of use for the suture to make Branches for Wood,

and to take away some that are grown useless.

All these are laid down in four Clauses.

1. Remarks generally common for all forts of Fruis-

2. Remarks that are peculiar in every Year to the first pruning of Stone Fruit, especially Peaches and Apri-

3. To the second and third pruning of Stone-Fruits,

as well Espaliers as Dwarfs.

4. For trimming of Buds and useless Branches of both.

CHAP. XXIX.

Common Remarks for certain singular cases relating to the Pruning of all manner of Trees.

HIS Chapter shall be without Order or Connexion, every case being singular, and so collected.

1. Observation.

When a Branch well plac'd, either against a Wall's or in a Dwarf, hath shot some salse Wood, neither pro-

per for the Figure or Fruit, let them be cut off within the thickness of a Crown piece, or slopingly; tho it's best done at the first appearance in the Summer, by breaking off the Bud.

2. Cut off all Branches that shoot from a hard knob.

upon which the Stalks of Pears did grow.

2. Do the like by those which proceed from a short streight Branch like a Spur, tho' the Spurs are common and good to be preserved, yet the Branches growing from them, will never be good for any thing; if it produce more, cut off the Spur it felf.

4. Pruning some weak Branches may be as well perform'd by breaking them only at the end, as cutting

them with a Knife.

5. The Cock spur, or dry dead parts of Branches that remain where a Branch was shortned above the next Eye or Shoot, should be cut off always, tho' in

Peach trees it may fometimes be hurtful

6. When a Tree in its first Years hath produc'd Branches of moderate vigour, and afterwards purs forth strong ones well plac'd, tho' of faite Wood, these latter thay be us'd as the foundation for the figure of the Tree, and the other suffer'd a time for bearing Fruit, but if they come not well placed, cut them off, in hopes next Year of new ones better.

7. When an old Tree shoots stronger Branches tewards the bottom than the top, and the top be in an ill case, cut it off, and form a new Figure from those lower ones; but if the Top be vigorous, cut off the lower, unless well plac'd to continue for the benefit of

the Tree.

8: When little and weak Branches shoot from the like, and the third Shoot is strong, yet use them as Branches of falle Wood

9. The order of Nature in production of Branches and Roots, is to fend forth a leffer than the Branch of which it comes; if such prove thicker than the Stens

out of which it ariseth in Branches, use them as false Wood; in Rooss it's not material, the thickest being the best; and in Branches, if the Scituation savour the Figure, you may preserve them.

10. Consideration must be had (in Pruning) of the place from whence Branches proceed, as to be good

and fit to answer the end.

11. Likewise regard must be had to the effect of former pruning. in order to correct the defects of it,

or continue its Beauty.

12. Dwarf Trees not being supported by a Wall, if they are likely to bear more Fruit than they can sustain without breaking the Branch, care must be had to lessen the weight, by taking off some bearing Buds or Fruit.

13. If a large old Branch of a Peach or Plum Tree be shortned, it will not be apt to put forth young fresh Shoots, the Sap not easily penetrating a thick hard Bark; however other Branches which are left, may be better supply'd with nourishment. But Apricot Trees, or young Peach Trees, are apt enough to put forth fresh ones,

14: In vigorous Trees the weaker Branches are the Eruse bearers: In weak Trees, the stronger chiefly; therefore in the latter prune off the seeble and small.

15. In vigorous Trees, three Branches (which are good ones) may put forth at one Ere; generally the two fide Branches are proper to be preserved, and the middlemost cut off, and that in May or June.

dispos'd, if tack'd while young; if they be grown too ftiff and unfir, cut them off, and expect others that

may do well.

17, Tho' it be disagreeable (either in a Wall tree, or Dwarf,) to see a thick Branch crossing the middle of the Tree, yet if it be apply'd to fill up an empty side, it may be permitted; Niceties of Position are not-much to be observed in Fruite bearing Branches.

18. It's

122 The Complete Gard'ner. Vol. II.

18. It's difficult to strengthen weak Branches with out cutting away others that are superior to them, even the upper part of that from which it shoots, tho Nature sometimes doth it her self.

19. As to the pruning vigorous Peach Trees, it's necessary to defer the first pruning until they are ready to blossom, the better to know which may be most likely to bear Fruit, and then to shorten them as they

may require.

20. Fruit buds that are nearest the ends of Branches are commonly thicker, and so better sed than others, therefore for weak Trees it may be best to prune them early, that the Sap may not waste it self on such parts as must be retrench'd.

21. A Wall fruit-tree should be quite untack'd before you begin to prune it, for hereby you may order it to a better Figure than if the old Tacks remain.

22. It is often necessary to untack, both in order to make the Figure equal, and to remove Branches that are crept behind the Props or Stays; visit therefore your Trees often in May, to prevent such disorders, and to remove languishing or other Shoots that would cause consustant.

23. A multitude of Branches in the first Year is not always a fign of Vigour; but if they prove weak, an ill Omen, and token of Infirmity in the Rooes.

24. When either a Dwarf or Wall tree is great and old, it feldom shoots green Branches, and therefore faults are not so easily committed in pruning it, if the Dwarf be but kept open, and the Wall-tree have a good Figure, saults arise most where the Tree is vigorous, and produceth more than is expected.

25. We can only judge of the Strength or Weakness of Eranches by comparing them with others on the same Tree, the part on which they grow, and the nature of the Tree making difference; the neighbourhood of one very thick renders another, that is not so thick,

weak;

weak; as meny weak ones render another that is not fo weak, thick.

26. This Rule is considerable, for sometimes there is an extraordinary length and pretty thickness, which yet ought to be look'd on as weak or small.

27. When Branches are very stender towards the ends, 'tis a certain sign of Weakness, and ought to be shortned; and if thick there, the contrary is as sure.

28. The farther a weak Branch is distant from the Trunk, the less nourishment it receives, and is therefore to be shortned; thick Branches the more distant from the Heart, receive the more, and are therefore to be removed, that the Vigour may extend it self to the middle or lower part of the Tree.

29. From some Trees, especially Pear Trees, sometimes proceed Horizontal Branches, admirable to be pre-

serv'd, either shooting inwards or outward.

30. Some Branches may seem proper for Wood, to establish the figure of the Tree, yet it they prove of no better growth than Wood-branches, they must not continue. So that if better can be produc'd to supply their places, they are not to be relyed on.

31. When a Tree, especially Peach and Plumberee, ceases to put forth new Branches, they must be look'd upon as decaying Trees, and another prepar'd for its place; in the mean time cutting off all that are sapless.

- 32. A Branch for Wood must never be prun'd without occasion require it: As when a low Standard is hurt by a Neighbour that overgrows him, in such case some Branches that anoy the other may be prun'd and lest to bear Fruit at greater height than otherwise they ought, that you may receive some Fruit before they are quite cut off.
- 33. Thick Branches that grow from the ends of others tollerably thick and long, must be cut off short, that others may put forth in their stead; for if they were continued and pruned according to ordinary method, they would grow long and naked.

 34. The

124 The Complete Gard'ner. Vol. II.

34. The cutting thus short and stump-wise is generally used, where a Branch that was weak and long is grown vigorous, and puts forth at its end two or three strong Branches; it should have been shortned while it was weak, and it must be served so yet.

35. If the Branch cut stump-wise hath produc'd no Branches for Wood, but a thick Branch at or near the place of the Stump, it must also be cut stump-wise, unless the old one were lest too long, which then ought

to be cut again.

36. If an old well liking Tree be disorder'd with false Wood, by ill pruning; take it lower by cutting off a Branch or two yearly, 'till it is sufficiently shortned, if it be a good Kind worth preserving; otherwise graff on it a better fort.

37. Some Trees put forth so vigorously, that they cannot the first year be reduc'd to a small compass, such must be allow'd to extend themselves, or else they will produce false Wood; afterwards you may reduce them.

38. A vigorous Tree can never have too many Branches. if well order'd nor a weak Tree too few.

39. The Branches of falle Wood, or Suckers, as to Peach-trees and other Stone Fruit, are not so defective of Eyes or Buds, as those that grow on Kernel Fruit Trees; If there be a small number, manage them as Pear-trees in the like case; but if many and those on the lower part of the Tree, some of them may be prepar'd to renew the Tree.

40. All Trees have a Branch or two if not more, predominant; where the Vigour is equally divided, it's best; but if it incline to one side more than ano-

ther, it's very faulty.

41. A Wood Branch on the infide of a Dwarf is wel-

come, if favourably plac'd to supply a thin side.

42. Fruit-buds of Pear and Apple trees fometimes form themselves the same Year in which the Branch

they

they are adherent to is form'd, as generally all the Buds of Stone Fruit do; but for the most part it's two or three Years or longer, before the former come to perfection.

43. Shoots put forth in Autumn are always bad; and

must be taken off.

44. It is in the Gard'ners power to make Fruit-buds grow where he pleaseth, but not when he pleases.

45. If a thick Branch, being prun'd, shoots forth three, respect must be had to their thickness and strness for Fruit, and to maintain the Figure, and accordingly to be retain'd or cut off.

46. Wall-Stone-fruit-trees do well in putting forth fide Branches on Shoots of the same Year, for most Trees

are too apt to shoot upwards.

47. Never preserve sapless Branches.

48. A Dwarf tree of the Beurre Pear, when it bears must be prun'd shorter than others, lest the plenty and weight of its Fruie cause it to spread or open too much, which is no pleasing Figure.

49. In May take care that good Branches of Wall-fruit creep not behind the Supporters or Lettice frame.

50. A languishing Pear-tree may be restor'd by pruning and removal in better Ground, but never a

Peach tree, especially if Gum appear.

5 1. If a young Dwarf-tree have been spoil'd by Pruning or Accident, that it's thinner on one side than another, on which it change to put forth a Branch (tho of salle Wood) it may be allow'd to be sontinued of greater length, than otherwise the general Rules do admit.

52. When a Tree forms many Branches, some strong, others weak, it may soon produce Fruit; but if sew, and those strong, it produceth no Fruit, 'till in time it's grown fuller of Branches that abate its vigorous Shoots.

53. When Trees (by reason of their Vigour in growth) do not bear Fruis, leave upon them a great

126 The Complete Gard'ner. Vol. II.

deal of old Wood, avoiding Confusion as well as vacuity.

54. It's good to review presently after pruning, to amend some faults that probably may be committed.

55. When a Tree puts forth much stronger Shoots on one side than the other, a great part of the strong Branches must be cut off close to the Body, or some of them stump wise.

. 56. In all forts of Trees allow less length to the weak

than strong Branches.

57. It is common upon all Trees (especially the more ancient) to find weak Branches which want nou-rishment, therefore at the grand pruning, or oftner, shorten some, and diminish others; or sometimes a superior Branch that is too vigorous, whereby the weak may be better replenisht.

58. When an upper Branch requires shortning; cut it close to another, that it may heal over; but when a lower is cut off, do it sloping, or at a little distance,

that a new one may grow out of ir.

59. When a strong Branch is cut pretty close, and produceth nothing but weak ones towards its end, 'tis not likely to make a good Figure.

60. If a young crooked Tree produce a fine Branch below the crook, cut the Head off close to that Branch

of. If a thick Shoot put forth on a Wall tree, it may better be preserved on it, the ill placed, than on a Dwarf, because by nailing Ligatures, it self, or those that grow from it, may be turned often to a convenient place, which cannot be so well effected on Standard Dwarf Trees.

62. The five, fix or feven Inches be usually the proper length to leave Wood-branches at; yet very often they must be lest longer or shorter as occasion requires, upon the consideration of the vigour or weakness of the Tree, thickness or smallness of the Branch to be cut, the sullness or vacuity of the place

of

Vol. II. The Complete Gard'ner. 127

of its polition, and the height of other Branches upon the same Tree.

63. The Objections against skilful Pruning deserve

64. When a fine Fruit-branch shoots many others, which seem fit for Fruit, if they cause no Consusion, and the Tree hath vigour, particularly in Pear Trees,

they may be preserv'd.

65. It happens sometimes (especially upon Walltrees,) that sometimes a vigorous Branch, after it hath put forth the same year of its growth small Shoots towards the Head or end, may also shoot stronger afterwards below; these last may be preserved for Wood Branches, and therefore to be shortned, and the other looked on as Fruit branches.

66. There's no Scruple to be made, even in old Trees; elpecially Pear, Apple, and Apricot Trees, of abating thick Branches on certain fides, that by ill ordering prove too long and thin; tho' it be not convenient, without absolute necessity, to cut many thick Branches which stand over weak ones, shot from the same part, lest the Sap which sed the larger, slow so plentifully into the lesser, that it cause them to put forth much salse Wood, and Suckers.

67. Branches shot from the ends of others are commonly good Wood, yet sometimes it happens others

wife, and then must be corrected.

CHAP. XXX.

Particular Remarks for the first Pruning, yearly to be perform'd in February and March, upon Trees of Stone-Fruit, especially on Peach and Apricot Trees, either Dwarf-Standards or Wall-Trees.

Ruit-branches of the Trees above mention'd, are but of a small continuance, many of them perishing the first Year in which they produce Fruit, and even without it, if the Blossoms were destroy'd; these must be cut off, unless you find they have put forth Shoots for Blossoms for the succeeding Year.

It is not so with the Fruit-branches of Pear and Ap-

ple-trees, and even Plum trees.

The Curious ought to be pitied, whose Trees are planted in cold ill Ground, or Ground worn out.

Weak Branches must be preserv'd with care, (the length proportion'd to their strength) for the visible Hopes of present Fruit; and at second Pruning, if occasion requires, more boldness may be taken, but little hopes is to be had of them after.

Strong Branches are to be look'd upon with relation to the future, and therefore cut short, to produce others of both Kinds, and fill up the Vacancies where

those that have ceas'd bearing are cut off.

Trees of very vigorous growth, are not apt to bear Fruit, so that on such it may do well to leave Branches of a moderate thickness, and long, which may produce, probably, Fruit bearing branches the succeeding Year.

When a Peach-tree ceaseth to put forth Branches

for Wood, provide one to succeed him.

If an old Peach eree shortned, hath put forth several good Branches, order it as a young planted tree is already appointed to be, only leave the Branches longer.

Where

Vol. II. The Compleat Gard'ner.

Where Walls are not above fix or feven Foot high, the Trees planted against them must be at greater di-Stance than ordinary, and the fide Branches suffer'd to grow long, if the Tree be vigorous, even to a Foot and a half in length.

CHAP XXXI.

Particular Remarks upon the second and third Pruning of Stone-Fruit.

His fecond Pruning is to be perform'd about the middle of May, and concerns not thick Branches, but the weak, that were left at the first grand Pruning, in hopes of Fruit upon them, which Branches

produce different effects. As,

1. The most prosperous Fruit and fine Branches, in the best part of their extent, having Fruit that lies fo close, as to be likely to obstruct one another in their growth, some must be taken away: And in case the multitude of young Shoots, may be likely to bring confusion, some of the meanest and worst plac'd may be cut off.

2. Where there is much Fruit and no fine Branches. but weak and useless: There some of the Fruit thould be taken off, leaving that which is fairest and best plac'd and the Branch it felf shortned: If the Fruit grow on the lower part of the Branch, cut it off close to them.

3. Where you have no Fruit, and yet many fine Branches; some of these ought to be preserv'd for Fruit next Year, but if any one be more luxurious in its growth than others, especially toward the end of the Branch, cut that clear off; but where there's neither Fruit nor good Shoots, cut off fuch a Branch elose to the lowermost Shoot it hath put forth.

4. If the Branch have only produc'd a fingle Shoot at the end thereof, with much Fruit every where, if

ìc

130. The Compleat Gard'ner? Vol. H.

it be not so strong as to be likely to become a Branch of Wood; it ought to be preserv'd, and the small ones among the Fruit cut off; but if it incline to be a

Wood Branch, shorten it.

5. If it be along Branch, and hath only two or three Fruits towards its End, and a few Shoots in its Extent, unless for particular Reason you would preferve the Fruit, shorten such a Branch, and preserve its best Shoots.

6. Such Branches as are destroy'd by Cold or Gum,

cut off as far as they are dead.

If any thing have hindred the performance of this fecond Pruning in May, it may be done till the middle of June 2011 ?

CHAP. XXXII.

Of the different manners of ordering a Peach-Tree in the Summer time:

Gard'ners observe three different ways herein.

1. Some pull or tear offall young Shoots which grow before and behind, and leave but few others:

There feem to blame.

2. Others cut off those Shoots within three or four Eyes or Buds of the Branch they grow on; which

renders the Tree ugly and difagreeable.

3. The last manner is, to preserve all the good Branches and nail them up neatly, leaving them to the time of general Pruning, at which time you may preserve those you like best; which is the Course the Author always took.

CHAP XXXIII.

Of the Trimming of Superfluous needless Buds and Sprigs.

THereas Pruning serves only to shorten or take away old Branches, that either by their length, scituation, or number, annoy a Tree; fo this Trimming or Picking, is entirely to remove young Branches of the same Year, either thick or small, growing improperly, or to cause confusion or prejudice to the whole Tree, or the Branch on which they are grown.

The time for it is all the Summer, as occasion requires; the fooner the better (if it need it) to prevent the growth of those useless Shoots that waste a great deal of Sap, and this should be performed on young as well old Trees.

It is not easie to set down precisely what Branches must be thus Prund or Trim'd, but a skillful Gardiner, who by the Rules foregoing hath form'd the Idea of a fine Tree, and concluded what should remain for Wood and Fruit-branches, will eafily perceive what's fit to leave, and what to take off, be it either Buds before they are thot, or Shoots lately put forth; and observing the Directions before mention'd in Pruning, he'll need no farther affiftance in this matter.

eradic sold

C H A P. XXXIV.

Particular Remarks for another material Operation, to be performed in the Summer upon some Trees, which is called Pinching or Breaking.

Pinching, in relation to Gard'ning, is to break defignedly a tender Sprig of any Plant what soever, without the help of any Instrument, only using the Nails of two Fingers; your Shoots so served, are not so apt to die and grow black, as when cut with a Knife: It may be practis'd on Buds or tender Shoots in April or May, and sometimes in June and July: 'Tis commonly practis'd on the Shoots of Melons, Cucumbers, &c. not on Fruit-trees, but our Author us'd it on Pear, Peach, Fig, and Orangetrees; but what's here mention'd concerns only the two first.

This Operation is to be perform'd upon thick new Shoots, within two or three Eyes of the Branch they grow out of; and the Effect is, that instead of one strong Wood-Branch (that may be obnoxious) a vigorous Tree will put forth two or three at those Eyes left; and the Sap being now divided, the Branches may be lesser and fit for Wood and Fruit, if they are well plac'd; but it's chiefly to be practis'd upon the thick Branches on the top, which would remain useless from their Situation, and yet spend much Sap.

This is not to be practis'd on weak Branches; for if they put forth more, those probably be weaker

than the Stem so pinched.

CHAP. XXXV.

Of what is to be done to some Trees being extraordinary vigorous, not bearing Fruit.

Several Expedients and Remedies have been proposed for curing vigorous *Trees*, that produce much *Wood* but little or no *Fruit*, which upon tryal have had no fuccess; As,

To bore a Hole in the Stem of a Tree, and put a Peg of dry Oak into it; to split one main Root, and put a Stone into it; to Prune at the rime of the de-

clining of the Moon, &c.

The manner of Pruning, (as is before directed) may be a great help to bearing Fruit; but the most effectual Cure, is to open a part of the Ground, so as to come at the Roots, and cut off one, two, or three of them on one side, which will put a stop to the great affluence of Sap. Some have used to take up the Trees and replant them, but this is too violent a Force upon them.

CHAP. XXXVI.

Of the Conduct or Culture of Fig-Trees.

THE difficulty of preferving the Fig. trees from the Cold, is the chief Reason why to few of them are propagated in our Climates, for in hot Countries they abound, and that to great Profit: But since their Fruit is much desired by some Persons, they may propagate and maintain what number they please securely, and to bear Fruit well in Cases with little difficulty, after these following Directions.

1. For the *Earth*, it need be only common *Gurden*Mould mixt with an equal quantity of rotten *Dung*,

which must be ram'd hard to the bottom of the Case, and the Tree fet very near the top, with Mould more loosely laid about it.

2. Their Roots, instead of being hard and thick, are fost, slexible, and slender, easier to be ordered in Cases than Orange-trees, which yet thrive well in

3. The Fig-tree puts forth abundance of Roots. so that it's easie for them to feed the top and grow vigorous, and that with little Earth, if well watered.

These are nothing so tender as Orange-trees, which are Green, and growing as well in Winter as Summer. and therefore an ordinary Confervatory will fuit with them, be it Cellar, Barn, or Stable, and they need not be put in till the end of November, unless Frosts are earlier than ordinary, and that without any great care, culture, or closeness, unless in extream Frosts, and to be taken out again in the beginning of March, or later, as the Season happens, and if it permit, the fooner the better, to inure them to the Air, and that the Sun-beams and Showers of Rain in March and A. pril may hasten their putting forth: being taken out of the Conservatory, let them be put close under a Wall expos'd to the East or South Sun, and so continue till the beginning of May, in the mean time if Frosts happen, let them have some coverings in the Night, because the Fruit hath no Leaf to shelter it. and afterwards the open Air is best, so it be not much expos'd to Cold, but fayour'd by the help of Walls or other Shelter.

At their first putting out into the Air, let them have a good Watering, and they'll need no more till the middle of April; in May give them Water once a Week, and towards the middle of Fune frequently almost daily; the Sun having great influence on the Roots, by reason of their being thus in Cases, causes them to ripen fooner than those against a Wall, and commonly to bear two Crops of Fruit, one in June or July, another

Vol. II. The Compleat Gardiner. 135

in Septenber; for the better ripening the later, place

the Cases again under a warm Wall.

To supply and maintain the Stock (for you cannot expect they should be fit for Cases above fifteen Years) they are easily cultivated: in the middle of March take up young Fig-Trees, either Suckers from the old, or Lavers that are Rooted, and after having shorten'd all the Roots and Stem, put them in earthen Pors about four Inches deep, and place these in a hor Bed, after the great heat is pretty well over, let them be watered, and the Bed, refresh'd on the sides to continue the heat; in two Years time they may require to be shifted into bigger Pots; which do in the end of the Year, and as they grow bigger let them have bigger Cases once in three or four Years; in thisting remove not the old Mote or Mould from the Roots, but let the like Rule be observ'd as herein is at first directed: After Cases are come to eighteen Inches square, the difficulty of removing them will be confiderable, if you should yet put them in some enlarged, unto twenty two or twenty three Inches square, otherwise you might continue them longer in Cases: When they are grown too big for Cases they may serve, having their Tops and Roots well shortned and prund, to see essential. where.

Fig-Trees, by reason of their great expence of Sap in Leaves, Fruits, and thick Shoots, require watering all the Summer, tho' little or none in the Winter; this is to be understood of those in Cases, for those that grow on main Land will root so deep, that part of their Roots may continually have moisture, unless in a very dry Season; if they want it, the Fruit will not fill, but drop off before it comes to Maturity.

The Figure of Fig-Trees will in no place answer that of other Fruit-Trees; their Beauty in Cases consists in being real Dwarf-Trees without a middle Stem, if it may be, not shooting too high, not being too much extended, with bare Branches which they are subject unto, unless great foresight be had.

L. As

136 The Compleat Gard'ner. Vol. II.

As to the Trimming and Pruning these Trees, it's necessary yearly towards Spring to cut off all dead Branches, which they are more subject unto than any Trees.

As to Fig-Trees placed again a Wall: In the Summer time do best to have some liberty from the Wall, and not close tack'd, as other Fruit-Trees ought to be, but rather upheld by Poles or Perches fasten'd to the Wall at a little distance, tho' in the Winter some strangling Branches ought to be cut off or nail'd closer, the better to place before them a desence of thick Mat or Straw upon a Frame to preserve them from the Cold, the North-east Winds, and sometimes the South proves Mortal to them, and these are to be

continu'd until April or very near it.

Another material thing is, every Winter towards the begining or end, to take up all Suckers from the Foot near the Root, and these may be of good use to raife more Trees, being planted in a Trench near a Wall and covered in the Winter: And the Branches of the Tree ought not to be permitted to grow too high, in order to keep them more full, therefore the new thick Branches ought yearly to be shortned, to a Foot or thereabout and the Bud at the end of the Branches to be broken off in the Spring time, that instead of one fingle Branch it may have two, and it may cause them to shoot out Figs the earlier, and so the sooner Ripe, all furtherence thereto is necessary in our Climates; the same course of pinching off End-Buds is very profitable in Summer also, and weak Branches are to be cut quite off; for contrary to most other Trees, the thick and ftrong Branches of Fig-Trees bear Fruit, and not the small; but if for want of others any weak Eranches are preferv'd, they must be much fhorten'd.

As to Dwarf-Fig-Trees out of Cases, they are trouble some to be kept, should be covered in the Winther, and ripen later than against the Wall.

CHAP

CHAP. XXXVII.

Of the manner of Pruning pretty old Trees.

There are three different states which well grown Trees arrive at. First, Vigorous Second Weak;

Third, in the Mean,

As to the Vigorous, respect in Pruning must be always had to continue or amend the Figure, and as the Figure will bear it, to leave the strong Branches long, viz. a Foot and half, or two Foot, and cut off few but such as grow outwardly, to cut them slantingly within a Bud or two of the Stem, and inwardly within the thickness of a Crown piece.

When old *Trees* are very weak, commonly the best expedient is to *Plant* new ones in their places; but if Persons will preserve them they must disburthen them extreamly, by leaving tew *Branches* for *Wood* upon them, and to shorten those to sive or six Inches in length, and but very sew weak ones, and none that

are dry or over much wasted.

As to those that bear and prosper indifferently well, the Rules for young Trees are to be observed still, wherein the Beauty of the Figure is always to be respected, which in a Dwarf-tree it is to be low in the Stem, open in the Middle, round in circumference, many good Branches on its sides, equal in height and thickness. In a Wall-tree it is to be equally furnished on both sides, not to be let run up only, or too saft in the middle of it, nor yet too thin or sparing.

CHAP. XXXVIII.

Of defects of Pruning, in relation to old Dwarfs.

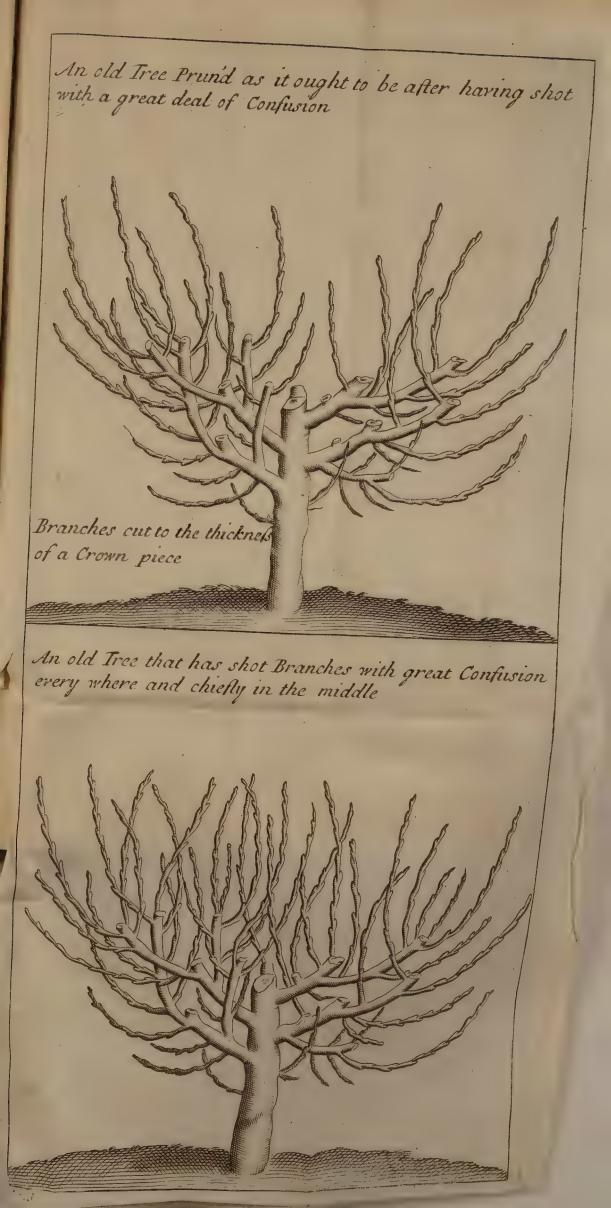

THERE a Dwarf-tree hath been left too high in the Stem, if it be old, the inconveniencies would be too many, if it be shortned; but if it be not above three year old, it may be shortned with advantage. If it be too thick in the middle, cut off clearly one, two, or more Branches that cause that fulness.

As to the defect in Roundness, a Tree is not easily amended, it must proceed from the not shortning those strong Branches it put forth first, and Year after Year as they onght to have been done; or elfe where a young Tree puts forth one strong Branch and one weak one, which were both left of a like length, (as they ought) but the strong over-growing the weak one, hath made it so unequal; tho' this strong. one, by often shortning where it ought to have been, might in time have been conducted to supply the Vacancies, by shooting Branches side-ways, which the weak one could not And this way the fourth defect. viz. of unequal Fulness on the sides, may be corrected.

CHAP. XXXIX.

Of defects of Pruning, in relation to old Wall Trees.

HE defects of Wall Trees must proceed also from the Negligence or Ignorance of the Gardiner in the first Years, by not shortning the top Shoot, and maintaining an equal Strength on both fides, The cure is to shorten them at two or three Years growth.

Of de

W HE in would be t not above t advantage. clearly one fulness.

As to the amended, those strong after Year where a yo one weak c (as they o weak one, one, by off might in ticancies, by weak one c viz, of une

diner

Shoot, and maintaining an equal outling on bourness, The cure is to shorten them at two or three Years growth,

growth, and tho the *Tree* be old, fome thick *Branches* may be taken off, with good effect in all *Fruit-trees*, unless old *Peach-trees* that have been grafted; but if it be a *Peach-tree* that came from a Stone, (tho old) it will shoot again very vigorously, for the fuch be longer than those grafted before they come to bear, yet they recompence it in lasting much longer.

So that for an old grafted Peach-tree, the grand Remedy of Mort'ning may not avail, but the ordinary Rules of Pruning are to be continued, and to refresh it with new Mould, and cut off some of the old Roots,

or else Plant a young fresh Tree in its place.

For fuch Trees as are short'ned, their young Shoots ought to be order'd according to the former Rules

touching young Trees.

The over fulness of one fide more than another, may arise either by permitting too many to grow thereon, or by cutting off several thick Branches near one another, whereby the Tree is apt to put forth many in their stead, which must needs cause confusion where they are, and likely to cause a defect in other places.

CHAP. XL.

Of the Pruning of Vines.

Pruning, it neither produceth so good, fine, or well fed Fruit, as it would otherwise do.

As the large Branches of Pear-trees, so the small ones of Vines produce no Fruit, but are wholly uscless, consuming a great quantity of Sap, and are therefore

to be cut off.

Two things are to be confidered in the Pruning of Vines, the vigour of the Plant, and the time; for the latter,

later, nothing need be added touching the time, to what hath been faid of the Pruning of other Fruit-

As to vigour, the number of Branches to be left must be proportion'd thereto, so it make not confusion in the most vigorous; and the thickest and best plac'd are to be preserv'd, and ordinarily their length to be limited to four Buds or Eyes cut off a tull Inch above the uppermost Eye, and slopewise, the Slope ending on that side the Eye grows on. These Directions are for Vines against a Wall.

The Branches of the foregoing Year are generally to be taken off, unless it happens (as often in old Vines) you cut off the old Stem (grown useless) unto the young, or have need to encrease the heighth or spreading of the Tree, and then they should be shortned to

the leaving only two Eyes.

In moderate Climates the Muscadine Grape requires a South Wall, and to grow to ten foot high, the same heighth is proper for Chasselas, Currans, early Grapes, &c. but those not against Walls much lower.

When the preceding Years Pruning hath produc'd three or four Branches (if the Vine be of the heighth above mention'd) the weak are to be wholly remov'd and two of the strongest sufficient to be preserv'd, leaving four Eyes on the uppermost, and two on the lowermost Branch, and the succeeding Year taking the uppermost off close, if the lower have produc'd two good Shoots, or else ro save what's wanting on the lower upon the uppermost.

When the old *Vines* begin to appear wasted, it's necessary to couch or lay down some young ones into the Earth, to beget new *Wood* from time to time, and also when any diminution of vigour is perceiv'd

to refresh the Roots with Dung or Soil.

If the Season be very dry, watering in August is of great advantage to the Fruit.

Vol. II. The Compleat Gardoner. 141

It the Fruit-bearing-branch be not very vigorous, it ought in fuly to be cut off close to the Fruit: In the heat of Summer some Leaves are necessary over the Iruit, to shelter it from the Sun-beams until it's halt ripe, and then bareness is requisite to bring it to maturity.

Birds and Flies of feveral Kinds, as well as Frosts

and Rain, are Enemies to the Grape.

Nets may be used upon the Vines to prevent Birds eating the Fruit, and Vails with Water and a little Hony or Sugar, hung with Pack-thread upon the Branches, will induce Flies to drown themselves, which (when a considerable number are in) must be emptied, and renew'd as before.

Q F

OF

FRUIT-GARDENS,

AND

Kitchen-Gardens.

VOL. II. PART. V.

CHAP. I.

Concerning the sare that is required to pick Fruits when they are too abounding.

HE intention of our *Culture* being to promote fine and fair *Fruit*, it follows from thence that there is fomething else to be done, which is here treated of

When we neither meet with Frosts nor bliting Windsin the Months of March, April, and May, it's certain that in some parts of the Tree, there will remain too much Fruit to appear beautiful, and large; as in relation to Kernel Fruit, viz. Pears and Apples every Bud commonly produces seven, eight, nine, or ten more or less: But as to Stone-fruit, except Cher-

ries, they produce but one Fruit upon one Bud, but their Fruit-bearing Branches are commonly burthen'd

with a great number of Buds close to one another, and upon every one of these Branches there may remain an excessive quantity of Fruit; so that the more Fruit there is upon a Branch of Stone Fruit, as Peaches, Apricots, and Plums, the less nourishment they have; the Sap distributing it self to all parts alike: The same may be said of Kernel-Fruit, which had there be na less number of Fruit upon each Bud and Branch, it would have been larger and better; for it's impossible to have Largeness, Goodness, and Beauty all at one time; therefore there must be a particular care taken to leave no more Fruit upon one Branch or Bud, than what may be judg'd capable to receive sufficient Nourithment, in order to produce beautiful Fruit.

In Fruning of every Tree there must be lest as many, if not more Fruit-bearing Branches, and more Buds upon it, than it seems to be capable of nourishing; having still a Precaution to the Hazards that are to be fear'd before the Fruits are safe, and being desirous to have the Fruit all beautiful alike; after the Fruit is well knit to make an exact view over every Bud and Branch, in order, as aforesaid, to leave no more Fruit than what may be judg'd capable of receiving

fufficient Nourishment.

When these superfluous Fruits are lest upon the Branches, Nature is disburthen'd of them by high Winds, which often happen in the Months of July and August, beating down as well the most beautiful and glorious Fruit, as the poor and meanest.

But sometimes these Winds do not happen, then the greatest of our Fruit which was knit, remains upon the Trees; and thus in the midst of Plenty, we have neither Beauty nor Goodness to recompence

our Culture

In this case it may be very proper to disburthen the Tree then on this manner, viz. to tarry 'till the Fruits' be pretty large in order to take away the worst, and leave that which appears to be best, which

144 The Compleat Gard'ner. Vol. II.

which will be about the end of May, or beginning of June, at which time the Fruit will be large enough

to facilitate our choice.

But this picking or culliug must be perform'd sooner in Apricots than in any other Fruit, because they ripen earlier, and in them we have a considerable advantage, in making Compots and wet Sweet-meats of the Fruit, which in other small Fruits we have not.

Care must be had to allow to all Fruits as much room as their Bigness may require when it approaches to Maturity, and particularly to those kinds of Stone-fruits which have short Stalks, as Apricots, Peaches, Pavies, &c. lest they should obstruct each other in growing; for its often seen that the largest destroy the smallest, so that the Nourishment they have received for two or three Mouths is all in vain; whereas, had these which are worst placed been picked off betimes, the small ones might have received the nourishment that was wasted on their Neighbour.

Autumn and Winter Pears, especially the largest; as the Beurees Virgoules, and Bon-Chretiens, do likewise stand in need of this picking or culling; for many of them being left upon one Knob, they seldom produce fine and large Fruit, but one smaller than the other, and ill favour'd, so that one or two upon

a Bud will be enough.

As for Summer Pears, as the little Muscats, Robines, Cassolets, Roussalets, &c. they need not be pick'd, but only to be us'd like Plums, and Cherries, they being Fruits of an ordinary bigness, and are commonly good of all Sizes, provided they be ripe, and not tainted

with Worms.

As to Stone-Fruit, except they arrive to their Extent and Bigness proper to their kind, they never attain the delicacy they ought to have, the Peaches remain shaggy and green, and don't quit the Stone clear; they are sowerish, and bitterish, the Pulp is rough, course, and often mealy, the Stone much larger than

Vol. II. The Compleat Gard'ner. 145

it should be, all which are certain Marks of an ill

Peach.

As to Winter Bon-Chretiens, in the Months of April and May, when they begin to appear knit, he careful to deftroy small black Caterpillers, which are very numerous about them at that Season, gnawing the Rind of those Pears, which is the reason they are often crooked and uneven.

CHAP. II.

How to uncover, at a proper time, certain Fruits which require it.

Ruits upon every Tree being thus pick'd, they thicken by degrees under the Leaf, forme more forme less, according to their Kinds; forme sooner and others later, according to their time of Ripening; and as the Red or Carnation Colour, are necessary to certain Fruits, which they may have if not hindred, so there are certain others that can never attain it, as the White Peaches, Vert Longs, Green Sugar-Pears, White Figs, &c. There is likewise others, tho' never so much covered, always receive their Colour, as Cherries, Rasberries, Strawberries, &c.

they can never attain it, without the reflections of the Sun lye directly upon them; therefore it's proper at certain times to remove fome Leaves which shade them too much; likewise these Fruits which are shaded too much, neither ripen so soon, nor have they the delicacy of Taste as those which are more expos'd.

As Colour renders certain Fruits more valuable, fo

Yet care must be had not to uncover them 'till they have attain'd their proper fize, and begin to lose the great Greenness they had 'till then.

They ought to be uncover'd by degrees, at two or three feveral times, in the space of fix or seven Days;

of the Sun would certainly occasion a great disorder, the tender Rind not being accustomed to the open Air.

But to render the Colour more bright and lively, it will be very proper to use a kind of Seringe, like unto a watering Pot, to water them two or three times a day during the great heat of the Sun, which softens the Rind, and is of wonderful use to that end, especially for Apricots and Peaches, and also succeeds well upon Bon-Chretiens and Virgoulee Pears, being somewhat whitish and having a fine thin Rind, they are apt to receive that fine Colour, which becomes them so well.

CHAP. III.

Of the maturity of Fruits, and the order which Nature observes in it.

INE Fruits having attain'd their Size and Colour, and arriv'd to their Maturity, it behoves us to improve those rich Presents which Nature and our

skilful Culture treat us with,

Care must be had to gather Fruits, and make use of them when they are entirely ripe, lest they be in danger of perishing; some thro Rottenness, which happens with most Apples; others by growing mealy, as in Peaches; some by growing soft first, as many Pears do, especially those which grow tender, as the Beurree; others by growing dry, as the Musk Pear, &c.

Care must likewise be had to know rightly when they are at Maturity; for some are about a Week good, and no more, as the Rousselets or Russelins; others not above a day or two, as Figs, Cherries, and most Peaches, &c. and some have a much longer time, a

Apples,

Apples, Bon-Chretien Pears, &c. a Month or fix Weeks, or more; which is explain'd more at large in the third Part, where you have the time of Ripening

fet down in every particular fort of Fruit.

As all Stone Fruits, some Summer Pears, and all Red Fruits, are in perfection from the time they are gather'd; it follows that none of them should be gather'd until they are at full Maturity, by reason that how little time foever their Maturity may last, they preserve themselves much better and longer upon the Stock, than they would do being gather'd.

CHAP. IV.

How to judge of the Maturity and Goodness of Fruit.

THERE are three Senses which have the Gift of judging of the appearances of Maturity of Fruits, viz. Sight, Feeling for the most part, and Smelling for some, but the Tast is the only real judge, as well of the Maturity as of the Goodness; tho' ie's fufficiently known there are fome Fruits which are neither good nor agreeable to the Palate, tho' actually ripe.

The Eye alone is fufficient to judge all Red Fruits, as Grapes, Cherries, Strawberries, &c. when they are all over painted with that fine lively black or red Colour which are natural to them, which shew them to be full ripe; or otherwise when one part of them wants it, or appears green, it shews them not to be at full Maturity: Feeling may serve very well for all

tender mellow Pears.

Sometimes both Feeling and Sight will be requifite, as for Figs, Plums, Apricots, and Peaches; but it is not a fair Colour that always denotes their Maturity; but when they are gently press'd, and come off with M 2

eafe

ease and leave the Stalk fixed to the *Tree*, it's a good mark of their being ripe. But as to Figs, they ought to be gather'd with the Stalks on them, for it adds to the beauty of their Figure, as also for *Cherries*, *Pears*, and *Apples* to be gather'd with their Stalks on, for it's an agreeable Ornament to them, and their being without it would be a defect.

As Sight and Feeling denote the Maturity of the aforesaid Fruits, so smelling with Sight may be admitted to others, as Mellons, for after their Colour, Stalk, and beautifu! Figure being approv'd, it will be very proper to smell to them before they are cut, to judge of their Maturity and Goodness; yet those that have the best Scent and Savour, are not always the best Fruit.

Having thus explain'd all the outward appearances of Maturity of the aforemention'd Fruits, yet the Taste must decide the Point; for let the outward Marks be never so favourable, yet if the Fruit don't please the Palate, the others are render'd useless: But, as is said before, Fruits are not all of an agreeable Goodness, that which pleases ones Palate may displease anothers.

CHAP. V.

Of the Causes of the Forwardness or Backwardness of Maturity in all manner of Fruits.

IR UITS ripen fooner or later, First, According as the Months of April and May are in Warm ness, or cause the Trees to blossom.

Secondly, According to what Exposition they are plac'd, whether East, West, or South, and particularly what Climate they are planted in.

Friuts that are knit betimes are ripe the foonest, and those which are planted on a Southern Exposure are fooner

fooner ripe than those planted on East or West, or on a Dwarf or Standard, the Sun casting a greater Reflexion upon them, than upon the others.

So likewise those planted in a light Earth, and a hot Climate, are sooner ripe than those planted in a

heavy wet Ground, or a cold Climate.

But supposing two several Grounds of two different Natures, viz. one light and fandy Earth, and the other a heavy clayey Earth, are so near one another and the Fruits of each Ground placed to one Exposition equally alike, insomuch that the Reslexion of the Sun can make no difference, yet those planted in the light soil will ripen the soonest. So that to have Fruits ripen early, is to plant them in a favourable Exposure, in a hot Climate, and in a light sandy Earth; all which renders the Fruit to knit betimes, and consequently will arrive to Maturity sooner.

CHAP. VI.

Of some particular Remarks of Maturity in every kind of Fruit, and first of the Summer Fruits, which ripen altogether upon the Tree.

B OTH Stone and Kernel Fruit ripen sooner upon a sickly Tree, than upon a sound one, and are commonly larger than those on a vigorous Tree, but that Largness is only a Swelling, or a kind of Dropsie, which is the reason that the Pulp of those Fruits are larger than they should be, and is generally insipid or bitter. Peaches that drop of the melves are commonly past Maturity, and consequently nought.

Summer *Pears*, as little *Muscats*, &c. the first Mark of their Maturity appears towards the Stalk, which must be a little yellowish; and for a greater

M 3 Mark

150 The Compleat Gardiner. Vol. II.

Mark full Maturity, that Yellowness must appear through a certain tann'd and ted Colour which covers all the Rind; and lastly, they must begin to drop of themselves, at which time it will be proper to gather and eat them.

'Tis not fo with finall *Peaches*, or to early or late Purple *Peaches*, nor to *Pavies*, they being *Fruits* which can hardly ever be too ripe, and are commonly very good when they drop; infornuch that when they drop without being shook, it's a good mark of

their Maturity as well as Goodness.

The feveral forts of Summer Pears which ripen in August, as Cuise Madams, Gross Blanquets, skinless Pears, the Orange Pears, Summer Bon-Cretiens, Casfolets, Robins, Rousselets, &c. Their Maturity is known either by their dropping, or not resisting when they are gather'd; or else by a certain yellow Colour, which appears in the Rind, especially near the Stalk.

Peaches are fit to eat when gather'd, and require no Store-houses at least to ripen them, for they never ripen off the Tree, so that they must not be gather'd before they are perfectly ripe; but a day or two of Repose in the Store-house, affords them a certain Coolness which is very proper for them, and that which they can't acquire upon the Tree.

CHAP. VII.

Of the Scituation that is proper for the Fruits that are gather'd, in order to preserve them some time.

N order to preferve Summer Fruits for two or three Days, (especially Peaches) they must be laid either in Closers or Store-houses, which must be very dry and clean, and full of Shelves, the Windows being always open,

open, unless it be in very cold Weather; you must lay a Finger thick of Moss upon those Shelves, which may ferve for a quilt, taking care that the Moss be very dry, and has no ill Scent, that every Peach so placed, may fink into the Moss, and lye softly, without being squeez'd by any of the others, for as it is with Mellons, so it is with Peaches, that they eat better after being gather'd a day or two, and laid at a distance from the Sun, than just after their being gather'd, at which time they are luke-warm.

They must be visited carefully once a day, lest there should appear any Rottenness, removing all that are in the least tainted, lest they should spoil the others; but all this must be done with a careful

and skilful Hand.

Peaches ought to be plac'd with that part downwards which the Stalk grows upon, for fear of bruifing them; and for Figs they ought to be laid fideways, left by brufing the Eye, they lofe their best

Juice.

Pears may be plac'd with their Eye downwards, and the Stalk standing upright for fear of being broke, Apples, if laid so carefully, may be plac'd either upon the Eye or Stalk; but they may be laid only upon one another, 'till such time as they are at Maturity, after which they ought to be plac'd in some better order; but beware of laying them upon Hay or Straw, for that gives them an ill Scent.

The best way for Grapes is to hang them up in the Air fastened to a Pack-thread, or about a Hoop, or

fixed to some Beam.

But if any Person is desirous to preserve them 'till Felruary, March, or April, they must be gather'd before they are persectly ripe, otherwise they are apt to rot too soon; Care must likewise be had once in two or three Days to pick off all the rotten ones carefully.'

M 4 The

152 The Compleat Gardner. Vol. II.

The greatest mark of Maturity in all manner of Apples, commonly confists in their being wrinkled; except the Apis or Ladies Apple, which never wrinkles, but is known to be at Maturity, by the green

Rind turning all yellow.

With these Precautions Fruit may be easily preferv'd as long as it will last, nothing will hurt it but the Winter Frosts, which when it once enters them, they retain no manner of Goodness, but immediately decay.

CHAP. VIII.

Of the Transportation of Fruits.

Eaches, Figs, Strawberries, Cherries, Rasberries, &c. in order to their Transportation from one place to another, require Water Carrage, or the Back or Arms of a Porter, for fear of jogging; but more proper on their Heads, as our Fruiterers in England commonly do: But if they be Peaches, they must be laid upon that part which is fixed to the Stalk; without touching one another, and be laid upon a bed of Moss or tender Leaves, laid pretty thick, and wrapt up in Vine Leaves, and fo order'd that they may not move out of their places. And in cafe feveral Beds be laid one upon another, a good ieparation of Moss must be laid between them: Or a reasonable quantity of Leaves; and the whole wrapt up with Cloath well fastned, in order to keep the Basket close and in good order. For Figs you must have Sives not above two inches deep, laying a Bed of Vine Leaves at the bottom, and place the Figs fideways, wrapping them up first asunder, one in a Leaf, taking care to order them fo well, and fo neatly close to one another, that their transportation may not

be able to remove them; and never to lay one on

the top of another.

This Bed being made, it must be cover'd with Leaves, and next with a Sheet of Paper, neatly fix'd about the Sive with small Pack-thread, in order to

keep the Fruit close.

Good Plums being laid up without any Ceremony. may be put up in any Basker, with Leaves at the bottom of it; the top must be cover'd also with Leaves. and afterwards with Paper, tying it close up as the former.

Common Plums may be transported in great Baskets, only putting Leaves at the top and bottom.

Apricots ought to have the same care us'd about

them as Peaches.

Strawberries may be put into Baskets made on purpose for them, laying Leaves at the bottom, and stuffing Leaves round the sides, covering them with a wet Linnen Cloath.

Grapes may be carried the same way as Peaches.

In order to transport our principal Fruits, if not above a days Journey, a large square Basker may be made close of Ofier or Willow, divided into several Stories on the infide, in the manner of a Press, this may open fideways like a Prefs, or on the top, and then having our Sives ready pack'd up, they may be put into this large Basket, placing the lowermost Story first, and then the uppermost.

If this Basket is not very close, there ought to be a Cloath, or fome fort of Covering thrown over it,

to keep the Fruit from Dust.

There may be a finall Padlock fix'd to the door of this Basket, with two Keys to it, the one for the Perfons to whom the Fruit is fent, and the other for him that fends it, by which means the Fruit may be fent fafe.

CHAP. IX.

Of the Store-houses or Conservatories for Fruits.

A S the Care and Skill of our Culture has yeilded us a fufficient quantity of each kind, both of Autumn and Winter Fruits, and that which is agreeable both in Goodness and Beauty; it follows, that we make some Provision whereby to preserve them as long as each kind may continue in Maturity: Which may be done in observing these following Conditions.

First, To establish a good Store-house free from

Frosts, which are a great Enemy to Fruits.

Secondly, That this Store-house must be exposed to the South or East, or at least to the West Sun, the Northern Exposition being pernicious to it.

Thirdly, That the Walls of the Store house should be at least twenty four Inches thick, otherwise the

Frost cannot be kept out.

Fourthly, That the Windows, befide the common Quarrels, should have good double Paper Saches, very close, and well stopt, together with a double Door, infomuch that the cold Air may not be able to enter in; for the least frosty Air that may be will certainly cause great Disorder; So that we cannot be too careful in this matter. But as the Frost is pernicious in this Store-house, so likewise Fire will cause a Disorder; so that there must be a double care to keep out the one without the other.

At this time it will be very requisite confantly to keep some Water in an Earthen Vessel in our Storehouse, to give us certain notice whether or no the Frost approaches us. It will likewise be of no less useto us, to have a good Weather Glass of the several Degrees of Heat and Cold, plac'd on the outside of the Nerthern Exposure, to give us a timely Precauti-

on of the approach of the Frost; and when it continues for two Nights together at the fifth or fixth, and even at the feventh or eighth Degrees, tho' the first Night may have done no harm, the fecond is much to be feared, and therefore the next Day we must use all the careful means we can to secure it with Quilts or Blanquets, or elfe a great deal of dry Moss to secure our Fruits from perishing.

But if it freezes fo violent, as that we are expos'd to danger, and having a good Cellar, it will be very material to remove them into it, 'till fuch times as

the violent Frosts are over.

In all fuch Cases care must be taken to replace them all in the same order they were in before in the Storehouse; and as foon as the Weather grows better, to remove fuch as are ripe or tainted, Kottenness being

the worst Accident that's to be fear'd.

Having made a Provision against Cold, we must also preserve our Fruits from all ill Tastes, as the neighbourhood of Hay, Straw, Dung, Cheefe, foul Linnen, especially that which has been us'd in the Kitchen, all which are very dangerous, and must not in the least be suffer'd near our Store-house, or Confervatory. A certain musty Taste, together with the Smell of Fruits that have been laid up long together, is likewise very disagreeable. And therefore,

Fifthly, The Store-house must not only have good Overtures, a high Ceiling, the height of which is to be from ten to twelve Foot high, but the Windows must be often kept open, that is when there is no fear of Cold, either in the Night or in the Day; because fresh Air from without, when it is temperate, is incomparable to purifie and re-establish that

which has been long inclos'd.

Sixthly, That neither a Cellar nor a Garret are fit to make this Conservatory; the Cellar a fort of mustiness, and moist Heat esfusing from it, which inclines the Fruit to Rottenness; and the Garret, because

of the Cold which eafily penetrates the Roof; and therefore a Ground Room is best, or at least a first Story, accompanied with other Lodging Rooms over

and under it, as well as on the Sides.

Seventhly, this Store-house requires many Shelves fram'd together, in order to lodge the Fruits separate one from another, the finest on the best side, and baking Pears and others on the worst; the distance of these Shelves is to be nine or ten Inches asunder, and about seventeen or eighteen Inches broad, that they may hold the more, and please the sight the better.

Eightly, These Shelves should be a little sloping outwardly, about an Inch in the Breadth, with an Edge upon the outside about two Fingers high, to hinder the Fruits from falling; the Fruits being not so much in fight when the Shelves are level: And when any of them are rotten, it's not so easily perceived, and that Kottenness commonly communicates it self to those that are about it, unless remedied at first.

Ninthly, That for fear of this Rottenness, every Shelf should be visited every other Day without fail,

to remove whatever may be tainted.

Tenthly, That the Shelves should be cover'd with fomething, as dry Moss, or fine Sand, of about an Inch thick, in order to keep every Fruit steady after it's plac'd as it should be, and to keep them afunder; for the Fruits must in no wife be allow'd to touch each other.

It's much pleafanter to fee them all in a row upon

their Basis, than to lye confus'd and irregular.

Eleventhly, and lastly, That care be taken to sweep our Conservatory or Store-house often, to suffer no Cobwebs in it, and to keep Traps for Rats and Mice; and it will not be amiss to allow some secret entrance for Cats, otherwise the Fruit will be in danger of being gnawn by those pernicious little domestick Animals.

The Conservatory which is particularly defign'd for Winter fruits, is likewise very useful for those of Autumn.either Pears or Grapes; and for Summer-fruits, either Peaches, Pavies, Brugnions, Plums, &c. thefe. as has been already faid, are much better a day after their being gather'd, than the very day, because they acquire a certain Coolness in the Store-house, which is a great Improvement to them, which they can ne-

ver have while they are upon the Tree.

The Vert Longs, Butter Pears, Vine Pears, Messer Johns, green Sugar Pears, &c. after these the Petit Vins, Lansacs, Marchionesses, Bergamots, and Amadots, the Besidery, and the thick Stalks, &c. are the first that pass during the Month of November. The Thumb (as is already faid, for the Butter Pears, Vert Longues, green Sugar Pears, and others which have begun to ripen in Ollober) denotes the time of their Maturity; as likewise the Petit Oins, Marchionesses, Russetins, Lansacs, &c. they being melting Pears. A whitish Colour which forms it self in the Melher Fean. a yellow Cast in the Amadots, thick Stalks, Besideries, &c. and a Moillure upon the Rind of the Bergamots, together with a little Yellowness which discovers it felf upon them, all these are certain Signs which inform us, without the help of the Thumb, of the Maturity of those five last kinds of Fruits, with examining and reviewing constantly, or at least every other day: This Reviewing must be continued for the following Months for all other Fruits; and in Reviewing remove fuch as begin to rot.

The Louise Bonne, Winter Thorns, Ambrets, Le. Chasseries, St. Germains, Virgoulees, dry Martins, and Spanish Bon-Chretiens, with the Fenouillet, and Autumn Calvil Apples, and some Pome d' Apees, and Reinettees, &c. all these kinds of Fruit ripen at the beginning of December, and a little Yellowness, together with some Wrinkles, discovers it self upon the fix first, by which we may judg, in case they do not resist the

Thumb, that they are fit to eat, but 'till then we must not venture to meddle with them: In cutting them the Knife will soondiscover their want of Ripeness. Those kinds of Pews are very subject to soften, and thereby are certainly apt to deceive those who do not strictly examin them every Day.

As to dry Martins, Spanish bon-Chretiens, and Portails, as soon as ever there appears the least Spot of Rottenness upon them, their time is come, and they are soon threatned with Rottenness, but with this Advantage, that they remain a pretty while in the

state of perfect Maturity.

The Fenouillet or Reinettee declare their Maturity as foon as they become extreamly wrinkled. The Apis declare theirs when their green Colour turns to yellow.

The Calvills feem to become lighter, and their Kernels loofen, and rartle in shaking when they ripen, they become yellow without wrinkling, which are admirable Qualifications in those Kinds of Fruit.

Such Fruits as have refifted the Thumb in December, will yield to it in their turns in the Months of January and February, but when the Winter Thorns are not able to change their Colour a little in those Months, they become mealy and insipid, and perish without attaining a perfect Maturity, which is a loss to the curious, since it is one of our best Pears.

The Louise Bonnes, and the long green Pears of September and October, feldom grow yellow, but they wrinkle and become foft, mellow, and agreeable to

the Touch.

Many Ambrets soften before they grow yellow, especially upon those Trees graffed upon free Stocks, that are too full, therefore they require Sugar to correct their Taste, which is not so good as it should be, tho' they be so very full of Liquor. The large Winter Muskets, and the Portail Pears do neither of them yeild to the Thumb; but the Yellowness of the first,

and

and a few Wrinkles, or fome Rottenness in the second, invite us to make use of their Goodness whatever it be.

A chief thing to be observed in ordering of the Fruits in the Store-house or Conservatory, is to place every Kind upon different Shelves, or if several forts upon one Shelf, to distinguish them by Divisions of Edges; and not only so, but to make a distinction of

Fruits of one Kind. As,

First, To place those that are fallen before their Time by themselves, out of Sight, they seldom looking well because of their being much wrinkled, some more and others less, according to their dropping sooner or later; but they ripen at last, tho' it be pretty long after others of their Kind, and pretty often they are incomparably good, especially when their Fall does not exceed above a Month before the time of the common gathering.

Secondly, Those growing upon Dwarf-Standards must be laid apart, as well as those of good Espaliers,

or good Walls.

The same Method ought to be followed for the Fruits of high Standards, and the same for the Fruits of Northern Espaliers, by reason that regularly the Fruits of good Espaliers and Walls ripen first, those of vigorous Dwarfs follow them, those of Dwarfs graffed upon Quince Stocks precede those that are graffed upon free Stocks, and those of infirm Trees precede both the one and the other,

The Fruits of high Standards succeed and oftenmix with these, and are the best of all, excepting only Plums and Figs. The Fruits of the Northern Expo-

fure ripen last of all.

"The Author here prefers the Fruit of good Efpaliers and high Standards to those of Walls, but

the Climate in England being so much colder than
that of Versailles, the hazard will be too great
for a Gentleman to depend upon any of the Win-

c ter

160 The Compleat Gard'ner. Vol. II.

" ter Pears for high Standards; notwithstanding in a favourable Year some Winter Pears, as the Ama" dots and other dry Pears, eat better from a high

" Standard than from a Wall.

Winter Bon-Chretiens and Colmars let all other Pears pass before them, and in the mean time the others begin to turn yellow and ripen, and to wrinkle a lit-

tle towards the Stalk.

When the Bon Chretien is perfectly ripe, the Pulp is almost melting, and when not, it remains very stony; some of them will keep till March and April; the Bugys, St. Lezins, and Martin Secs joyn with those; the Bugys in March and April are very delicious, with their tender watery Pulp, tho' a little sowrish. The St. Lezins with their firm Pulp, accompanied with a little Persume, also make some Figure, but it's very difficult to preserve them, because the least touch of Cold blackens them entirely, and renders them odious to sight, as well as disagreeable to the Palate.

As for baking *Pears*, they are good at all times for the end they are defign'd for, particularly when they begin to grow yellow; with this Provifo, that all fuch as are tainted with Rottenness must be laid aside, lest they should insect those that are sound: And thus the *Franck Real*, and the *Carmelite*, and especially the *Double blossom'd*, which are the best of those that are only sit to bake: The *Angober* and *Catillaes* may chance to acquire some Goodness, being season'd with Sugar, and the heat of the Fire; but they still retain a touch of Tartness, which can never agree with nice Palats.

Autumn Calvils and Reinets are admirable for preferving; the Fenouillets are not so good, by reason of their Sweetness; but the first have a kind of Briskness, which gives them an incomparable Taste.

CHAP. X

Of the Diseases of Fruit-Trees.

Ruit-Trees are subject to certain Infirmities that destroy them, which we may very well term Distempers; Yellow Leaves out of Season, new Shoots growing black, and dying on their Extremities in the Months of August and September; Fruits remaining finall, or dropping off themselves; which Distempers are so many speaking Symptoms of the Indispofition of the Foot. Among these Infirmities there are fome that may be cured with the affiftance of fome Remedies, and others which hitherto appear incurable. fince whatever can be done to them has still prov'd ineffectual.

In order not to omit any thing relating to those Accidents which our Trees are liable to without including fuch as proceed from too long Wounds of great Heat, of great Cold, and Storms, of Whirlwinds. Hails, &c.

In the first Place, there are Distempers common to

all Trees in general.

I Trees in general.

Secondly, There are some that are peculiar to eve-

ry particular Kind.

The common Distempers consist either in a defect of Vigour which makes the Trees appear in a langushing Condition, or else they are Storm'd by large white Worms, which are fometimes form'd in the Earth, and there gnaw the Roots, or the Bark of the neighbring Stem: These mischievous little Insects, which we call Tons; by degrees cause so great a disorder, that the Tree which is attack'd by them, and had always appear'd vigorous before, all on a fudden dies without any Remedy.

The peculiar Diftempers in Pear Trees against Walls, are when their Leaves, are attack'd with what

we call Tygers, Cankers, and Scabs in other Pear-Trees viz. Robines, small Muscadines, &c. Gum on Stone-fruit-Trees, especially Peach-Trees, which commonly destroys that part on which it fixes, either Branch or Stem; and when unfortunately it attacks that part where the Tree is graffed, which is often hid under the Ground, it spreads round about that Graft, without any bodies observing it, for the Tree, still continues in a good Condition while there remains any passage for the Sap; but finally this Gum hind ring the Sap from rising to the upper parts of the Tree makes that

Tree die fuddenly.

Moreover some Peach-Trees are also attack'd with Emets, and a small kind of green Flear, which sometimes fasten on the young Shoots, and hinder them from thriving; sometimes on the new Leaves, and cause them first to shrink, next to dry and fall: We have likewise Northeast Winds which blast, in some Springs wither, and as it were burn all the new Shoots, insomuch that the Trees on which this unlucky Influence lights appears dead, while others about them are green, full of sine Leaves, and continue to produce sine Shoots; Besides the most vigorous Trees are subject to have the end of their new Shoots intirely cut off by a little black round Insect, call'd Butter cutter.

Fig. Trees dread the great Colds of the Winter, which are capable of freezing their whole Head, un-

less they be exteamly well cover'd.

They are likewise subject in that Winter Season to have the lower part of their Steins gnaw'd by Rats and Melots, or Garden Mice, which make them pine and die.

Those very Animals, together with Laires, Earwigs, and Snails, likewise spoil the Fruits on the Trees, when they approach to Maturity, especially Peaches

and Plums.

Goose-berries have likewise their peculier Inemies,

which are a kind of small green Caterpillars, which form themselves towards the Months of May and Fune on the back part of their Leaves, and ear them to that degree, that those little Shrubs temain altogether bear, and their Fruit being expos'd to the great Hears of the Sun, is destroyed without being able to ripen.

Straberry-Plants in the Prime of their Youth and Vigour, are as it were treacheroufly attack'd in their very Roots by those wicked Tons which destroy

them.

" The Author here makes mention of the Tillage, " and hringing into order the several forts of defective " Earth, but fince he has treated of it heretofore, we " referr you to the first Part, where he treats more

" largely upon it.

When there is not Mould enough, it must be augmented either about the Roots, removing all the ill Mould, to put better in the room of it, or elie by laying new Mould over the Surface of it. The Mould being thus amended, without doubt the Irees will

thrive better in it, and grow more vigorous.

When the Diffemper is only visible by a certain Yellowness; as for Example, Pears grafted upon Quince-flocks, in certain Grounds always grow vellow, tho' the Ground feems to be pretty good; it is a good and certain Advertisement to remove them, and to place others in their room on Free-stocks which are much more vigorous, and agree better in an indifferent Soil than others.

When Peaches graffed upon Almond Stocks cast too much Gam in moist Grounds, others must be planted upon Phon-flacks, and when they do not thrive upon Plum-flocks in fandy Ground; only fuch must be plan-

ted there as are on Almond or Peach-flocks.

If the Tree appears over butthen'd with Branches. to as only to thoot very finall ones, it must be eas'd until it begins again to produce fine Shoots, by lowering,

the uppermost Branches, or by removing part of those

which cause a Confusion in the middle.

When the Diffemper proceeds from the Tree being ill-condition'd before it was planted, from its having a scabby, poor Foot, half dead for want, or from its being too weak, the best way is to pull it up, and to plant a better in the room.

If the Tree, being good of it felf, has been planted too deep or too shallow, or with too many Roots, the best expedient is to take it up again, prune the Roots anew, and replant it according to the Rules of

Ařt.

And to all these ends it is very necessary to keep always some dozens of good Trees in Baskets, to place new ones ready grown in the room of such as must be remov'd.

When the Trees are attack'd with forme Cankers; you must with the point of a Knife, remove the part fo tainted to the Quick, and then apply a little Cow-Dung to it, covering it with a piece of Linnen: a kind of Rind will grow over it, which will cover the Wound and so that Accident will be cured.

VVhen Caterpillers annoy a Tree, care must be ta-

ken to remove them.

When Rats gnaw the Bark, Snares and Traps

must be laid for them.

When the Diffemper is supposed to proceed from Tons, the Foot of the Tree must be uncovered to extirpate them absolutely, putting new Mould in the room of the old, after having shortned the Roots that are gnawn.

Among the incurable Diffempers, the first is old Age; for when a Pear or a Plum Tree has serv'd for Thirty, Forty, or Fifty Years, we may conclude that it has perform'd its part, and there's no hopes of a Return, so that it must be taken out, not leaving any of its Roots in the Ground, putting new Mould

into the room of it, in order to plant new Trees there.

Secondly, Another incurable diffemper is Tygers. which stick to the back of the Leaves of Wall Pear Trees, and dry them up, by fucking all the green

Matter that was in them.

The Author has tryed many Experiments for the destroying of these Tygers as imploying all manner of strong, sower, corrosive, stinking Lees, viz. of Rbue, Tobacco, Salt, Vinegar, &c. to wash the Leaves and Branches, as also Oil; he has likewise smoak'd them with Brimstone, burnt old Leaves, scrap'd the Back of the Branches and Stem, to which they stick; he has dayly endeavour'd to find out fome new Expedient, and after all, never succeeded in any of them: There still remains some of the Seed of that curfed Infect in fome part or other; and in the Months of May and June this Seed is hatch'd by the heat of the Sun, and then multiplies infinitely: And therefore one of these two things must be done, either no Pears must be suffer'd against a Wall, or in a Espalier, or else we must resolve to see those Tygers upon them, contenting our felves with burning all the Leaves yearly, and with cleanfing the Trees, as much as is possible.

Thirdly, Gum is an incurable Diftemper, which fastens to the Peach Trees, and other Stone-fruits. When it only appears on the Branch 'tis no great matter; 'tis but cutting the faid Branch two or three Inches below the part so distemper'd, where this Gangreen is hinder'd from extending farther, as it would infallibly do, if it stuck about the Bud or Graff, or all over the Stem, or on most of the Roots; and then the fole expedient is to loofe no more time. about it, and confequently to remove such a Tree out

of the Ground in the manner aforefaid.

A Wound sometimes proceeds from an external Accident; for Instance, from a Wound which has

N 3

been made by way of Incision, by a Scrach; and sometimes from an evil inward Indisposition; that Gunz is nothing but a spurred Sup, which is subject to Corruption and Rottennels, from the time it ceases to be inclos'd in its ordinary Channels which lie between the Wood and the Bark; in that case the Remedy is easie, especially when it happens only on a Branch, as is already declar'd in the preceding Article. When the Distemper affects, the Stem, it often cures it felf by a Knob, or a continuation of new Bark, which extends over the Bark so wounded. Sometimes it's necellary to apply a Plaister of Cow Dung over it, cover'd with a piece of Linnen until the Wound be clos'd: When the Gum proceeds from the infide, it's incurable on the Stem or Roots.

" The Author treats much of bear Cow Dung, as " a Plaister for all wounded Trees; but we have found e by Experience, that Cow or Horses Dung mixt " with Loam made up like graffing Earth, and workt " up with a little Tallow like Paste is of a much bet-" ter Nature for the healing of Wounds in all man-

er ner of Trees.

CHAP. XI, XII, XIII, XIV, XV.

THE Author in these five Chapters has made a long and tedious Discourfe, viz. of Graffs, of the kinds that are in use, of the proper Times to Graff, of the manner of performing all manner of Graffs, and which are the Stocks, that have natural disposition to receive some Kinds of Fruits, and no other: All which may be reduc'd into these five general Heads.

First, Of Graffs. First, Of Grays.
Secondly, The Kinds that are in use.
Thirdly,

Thirdly, The proper Times to graff and inculate. Fourthly, The manner of Performing all manner of Graffs.

Fifthly, The Stocks that are proper for each Kind

of Fruit.

THE PERSON NAMED IN First. Of Graffs. "Inoculating is one Kind of Graffing; and accordingly our Author has given it the true Term, by " calling it Graffing; but if we should term it so in " England, it would not be fo well understood, not " being a Phrase us'd in England; and therefore it " being perform'd at a different Season from the seve-

ral other Kinds of Graffing, and that it may appear " easie to all People, we have given it the usual "Termination in England of Budding or Inocula-

.c. ting.

Secondly, The Kinds of Graffs that are most us'd

in England, are these three, viz.

Shoulder Graffing, or Graffing in the Rind. Stock or Slit Graffing or Graffing in the Cliff. And Tongue or Whip Graffing.

Shoulder Graffing, or Graffing in the Rind, is that

which is proper only for large Trees.

Stock or Slit Graffing, is that which is proper for Trees or Stocks of a leffer Size, from an Inch or more,

or two Inches Diameter. And,

Tongue, or Whip Graffing, is proper for small Stocks, of an Inch, half an Inch, or less, Diameter; this last is the most effectual of any, and that which is most us'd.

Thirdly, for the proper Times to Graff; it's impossible to give any certain Directions for it, because of the variableness of Seasons; but the usual Times we graff in, in England, is in the Month of March, and sometimes at the end of February, according as the Season is early or latter. But the main Rule that we generally go by, is by the Ascension of the Sap,

when it begins to afcend from the Root into the Branthes; for the Graff being apply'd it receives all its due nourishment of Sap from the Root in its Ascen-

The proper time for Inoculating or Budding, is likewife according as the Season happens, it being early or late; but the usual time for Stone-Fruit, as Peaches, Apricots, and Plums that are budded on Plum-Stocks, is in July, and sometimes at the end of June, especially if the Season be early, and the Ground moist. As for Pears, the usual time of Budding or Inoculating is in August.

Note that Peaches that are budded upon Peach or Almond Stocks, are commonly budded in August, or the beginning of September, because the Sap continues

longer in those Stocks than in Plums.

Fourthly, The manner of Performing the several Kinds of Graffs, is a Work that is become so frequent in England, especially in this Age, that it is altogether needless to explain the manner of performing the several forts of Graffs; since there are few Gard'ners but what are capable of doing it; and also what can be said may be comprehended in this: That there must be a great care us'd to make the Graff and the Stock sit close to each other, and that both the Rinds may touch each other as much as is possible; which is to be compass'd by a good Knife, and a steady Hand.

Fifthly, the Stocks that are proper for each Kind

of Fruit are as follows.

For Apricots and Plums, the feveral forts of Plum-Suckers, or those which are rais'd from the Stone,

excepting the Suckers of Damsons,

For Peaches, Pavies, and Brugnions, the Trees or Stocks that are rais'd from the Stones of the several Sorts of their Kind, together with Almond Stocks, and the Suckers of Muscle Plum Trees, and Pear Plums, viz. of those Trees that were never graffed.

For Pears and Medlars, Quinces, and the Trees or Stocks that are rais'd from the feveral forts of Pears.

For Apples, the Trees that are rais'd from the fe-

veral forts of Kernels of their kinds.

For Cherries, the Stocks that are rais'd from the common wild black Cherries.

CHAP. XVI.

Of Nurferies and Seminaries.

UR Nurseries, requires good easie Soil, or Ground, well till'd having at least two Foot and a half depth, the Trees must be plac'd in Rows at three Foot distance, according to the largness of the Trees, and at a Foot and a half, or two, or three Foot distance one from another, according to the Proportion of the Sizes.

" Here the Author recommends the Suckers or "Wildings of Crabs and Pears out of the Woods to

" graff upon; but we find in England, that those " rais'd from the Kernels of each fucceed best, because

"they are not fo apt to run to Suckers, and spawn

out so extreamly.

First, For Pears, plant Wildings of Pears grown from Kernels, as also Quince Stocks, which must be

well condition'd both as to the Root and Stem.

Secondly, For Apple Tree Seminaries, plant the Wildings grown from the Kernels of their Kind, or rather Crabs, in the same order as is before mention'd.

Thirdly, For a Seminary of Plums, plant the Suckers of their feveral kinds, only excepting the wild

Damsons.

Fourthly, For good Seminaries, of Peaches plant the Suckers of St. Julyans and black Damask, and black Muscle and Pear Plums; observing as is already men-

tion'd.

170 The Compleat Gard'ner. Vol. II.

tion'd, to Plant the Suckers of those kinds which were never grafted, otherwise it will be the same as to plant of any other sorts of Plums; plant also Peach and Almond Kernels, for a Seminary of them.

The rest of this Chapter is only a definition of what has been already mention'd in the foregoing Chapter; only for Figs and Vines they are to be planted in a Nursery manner, but a greater distance,

and increased by Layers or Suckers.

CHAP. XVII.

Of the different manner of Lattices us'd to Pallisade.

UR Garden Walls ought to be plaster'd, to stop all the holes against Rats, Snails, Earwigs, and other Vermine, which destroy the best of the Fruit; which being done, you may bend or pallifade the Branches to form the Figure of the Tree as you please, by tacking them with shreds of Sheep Skin, or Shammy, or Lifts of Cloath, less than half a Finger's Breadth, and a Finger long: This fort of pallifading is very agreeable, but very tedious; thefe Shreds may last a Year or two, but the only Objection against them is, that sometimes Earwigs shelter in them in the day time, and come out at night to injure the Trees, and therefore some not liking these Shreds do fix Spikes from space to space into the Walls sticking out about two Inches to fasten Laths or Poles to them, others make a Lattice of Poles supported by Horse Bones or those of Oxen, fixt into the Wall, to which they fasten the Branches of their Trees; others fix abundance of Sheeps Bones into the Walls, at a small distance in a straight Line, binding every Branch of the Tree to one of these Bones: Some make them

of Laths nail'd chequer-wife, every space being about twelve Inches, these they fix to the Walls with Nails or Hooks, and is a very pretty good Expedient, but never looks gentile nor handforn.

Some for Cheapnels wie Brass or Iron Wire supported by flat headed Nails; others have been content only with straight Lines of Wire, either long-wise or cross-wise: These two last, the neat, are not good, being too weak and apt to gaul the tender Branches. and thereby occasions Gum, to the ruin of the Trees.

After all, the most convenient and most noble is a Lattice of quarter'd Wood, or Heart of Oak, every Pole being about an Inch square, and free from Knots.

and well plain'd.

You must have Iron Hooks of about a quarter of an Inch thick, and half a Foot long besides the end which turns freight up about an Inch and an half. the end which must be driven into the Wall must be forked to hold the faster in the Wall, into which it must enter four Inches deep; two Inches on the outfide will fuffice; they must be plac'd at three Foot diftance chequer-wife, beginning the first Row within a Foot of the Ground, continuing it to the Top of the Wall, the Hooks must be in a straight Line and Parallel to one another; the Poles may be of what length you pleafe, according to the height of the Walls, those that stand upright should be all of one piece if you can, if not you may joyn two or three neatly, tying them very close with a Wire.

Take the straightest and weakest to serve in a ftraight Line placing the but-end downwards, the itrongest must be imploy'd a-cross to support the

Work.

The fquares must be about feven or eight Inches, they do not well of ten or twelve, and five or fix are too little for Espalliers, they may also be us'd for a fort of Arburs that are now in fashion; the Square must be exactly measur'd, leaving an Inch between

172 The Compleat Gard'ner. Vol. II.

the Wall and the Lachs: When they are furnish'd, you may first paint them white, and afterwards with a grass green.

These Lettices are sometimes made for Counter Espalliers or Pole Hedges, about five or fix Foot high,

according as you pleafe.

In order to its being folid, it's necessary to drive Oaken Spikes into the Ground at five or fix Foot diftance one from another, about four Inches square, driving them about a Foot into the Ground, the upper end being pointed to last the longer, for if it were square the Rains would rot it the sooner; the Checquers must be like those of Espalliers, only with this difference, that in Pole-Hedges the Poles or Laths must be fixed with Nails into the Body of the Spikes,

which must be notch'd in order thereunto.

This Method of Pallifading has feldom or never been us'd in England, but it may be very proper for old Brick Walls, where the Joynts are at fuch a diftance, that the Trees cannot well be nail'd to them, or likewife for Stone Walls, where the Stones are so thick that they cannot be nail'd to any advantage for the good of the Tree. But more especially for Mud Walls that are made of Earth an Hay, such as are us'd in some parts of the West of England, and other Parts where Bricks are not plenty; because the Trees cannot so well be nail'd to such Walls, without something of a Lattice or Pallisade in this manner.

OF

FRUIT-GARDENS,

AND

Kitchen-Gardens.

VOL. II. PART VI.

Of the Culture of the Kitchen-Garden.

Theing necessary for a Gentleman's Gard'ner to perform with equal Skill, all the parts of Culture belonging to the Kirchen-Garden, that so he alone may be in a condition of furnishing his Master with all the Varieties which a good Kichen-Garden, can produce; without wanting at least any of those Productions that are of most importance.

To which end, I purpose here to follow exactly the Model and Platform I have already explain'd at the beginning of these Treatises of Gard'ning; in

Conformity to which, I shall fet down,

First, Every thing, general speaking, that should be in all forts of good and well surnish d Kitchen Gardens; to which I shall add a Description of the Seeds

and

and other things which ferve for the Production and

Multiplication of every particular Plant.

Secondly, I shall specifie not only all things that may be gather'd out of a Kitchen-Garden every Month of the Year, but also what Work Gard'ners are to

do in every one of those Months.

Thirdly, I will explain what fort of Earth or Soil, and what fort of Culture is most proper for each fort of Plants to make them excellent; and because fome of them are sown to remain always in the same place, and some only to be transplant elsewhere, and some again are propagated without Seeds, I will give Directions at the same time how to order all of them; as well in respect to the Seasons in which they are to be sown or planted, as the manner of their Propagation.

Fourthly, I will shew you how long each fort may profitably occupy its place; and which of them must be laid up for Winter Provisions; and which may, by the help of Industry, be produced in spight

of the Frosts.

CHAP. I.

What Things should be planted in any Kitchen Garden, of a reasonable Extent, to render it complemly furnish d.

A L. L. the World is agreed, that there are few Days in the whole Year, in which we can well be without the affiltance of the Kitchen-Gerden.

That you may therefore have at one view, the know-ledge of what composes this agreeable assistance, that may be drawn out of the Kitchen Garden; I shall here present you with a kind of an Alphabetical Inventory of all things which such a Garden should and may furnish us with, throughout the whole Year.

CHAP.

CHAP. II, III, and IV.

Concerning a description of the Seeds, and other things which contribute to the Production and Multiplication of every sort of Plant. Together with what sort of Culture is most proper for every sort of Plant.

LLELUIA, or Wood, or French Sorrel is a fort of Trefoil, that is multiplied only by Runners or Slips which sprout from the Foot of it, as do Violets and Daifies, &c .It bears a white Flower, but no Seed: When it grows old, it grows into Tufts; and being a Plant that grows in the Woods and confequently that loves the Shade, we therefore plant it along the fides of Northern Walls, at the distance of about one Foot afunder: The more we slip it of its Leaves, which is one good quality it has, the more fresh ones it shoots out. It is enough to fer it two Inches in the Ground. It lasts three or four Years without being renew'd; and to renew it, we pred do no more than to separate or slip out the great Tufis of it into several little ones, and replant them immediately; which is to be done in the Months of March and April: A little Watering in very hot Weather, and especially in fandy Ground, is a very welcome Help to them.

Ams is propagated only by Seed, which is pretty small and of a yellowish green, and is of a longish oval Figure strip'd, which oval is bunch'd on one side; it is much like Fennel-Seed; it is commonly sown pretty thin, either in Furrows or Borders; their Leaves are used in Sallads among other Furnitures; they run to seed towards the Month of August; and when their Stalks are cut down, they shoot out near Leaves the next Year, and are as good as the single, but however it is best to renew them every way Years.

Arrach, Orrach, or Orage, is propagated only by Seed and is one of the quickest, both in coming up, and running to Seel; which latter it does at the beginning of fune: It is fown pretty thin; and to have good Seed of it, we must transplant some of it in a separate place: The Leaves of this Plant are very good both in Pottage and in Stuffings; we use it almost as soon as it peeps out of the Ground, for it paffes away very quickly; and to have some the more early, we fow a little quantity on a Hot-bed. It thrives well enough in all forts of Ground; but yet

it grows more fair in good Ground.

Artichoaks are commonly multiplied only by Oeillitons or little Eyes, or Off-sets, or Slips, which are a fort of Kernel which grows about the Foot of the Plant, that is in that part which separates the Root from the Eye or Bud, out of which the Stem grows that produces the Artichoak; these little Eyes, or Off-sets, begin commonly to breed at the end of Autumn, or in Winter when it is mild; and shoot forth Leaves in the Spring, that is at the end of March, or the beginning of April; at which time we fearch about the Foot of the Artichoak, and separate or slip off the Suckers or Off-flips, in French called little Eyes, and that is called flipping or dif-eying. These Off-sets. to be good should be white about the Heel, and have tome little Roots; those that are black about the Heel are old, and produce but very little Artichoaks in the Spring; whereas others produce according to the Gardner's Intention, in August, September, or October.

Sometimes Artichoaks are multiplied by the Seed, which grows in the Artichoak bottom when they are fuffer'd to grow old, to flower, and to open; and lastly to dry, about Midsummer.

When we tie them up in Autumn, we wrap and cover them up at their whole length with Straw or old Dung, and so whiten the Cottony fides of their

Vol. II. The Compleat Gard'ner. 177

Leaves, to make Artichoak Chards of: For the Planting of them, we commonly make little Trenches, or Pits. about half a Foot deep, and three Foot diffunce, filled with Mould, placing two Rows of them regularly by a Line in each Bed, which is to be full rour Foot broad; and parted from next Bed by a Path full one Foot broad; these Trenches or Pits are to be made about half a Foot from the edge of the Bed, and Chequer-ways one towards the other; we place two Slips in a right Line in each space, containing between nine and ten Inches in length, and renew them once every three Years at least: Cut off their Leaves at the Beginning of Winter, and cover them with long dry Dung during all the very cold Weather, till the end of March, when we must uncover them, and flip them, if their Slips be yet big enough, or else stay three Weeks or a Month longer, till they be; then we must labour, and move the Earth well about them, and dung them with the rottenest of that Dung that ferved them for a Covering; water them moderately once or twice a Week, till the end of May, at which time their Fruit begins to appear; and from that time we must water them plentifully, that is, two or three times a Week, during the whole Summer, allowing half a Pitcher of Water to each Plant, and especially in Ground naturally dry. Those planted in the Spring, shall bring their Fruit to Perfection in the Autumn following, if well water'd; and they which do not, ought to yelld their first Fruit in the Spring following in case they bestrong enough to refift the sharpness of the Winter. Artichoaks have not only the hard Weather, and excess of Wet to fear, but they have the Field-Mice likewise for their Enemies, those mischievous little Animals gnawing their Roots in the Winter-time, when they find nothing better in the Gardens; and for that reason it's good to plant one Rank of Beet-Chard between two Rows of Artichoaks, that the Field-Mice finding the Roots

Roots of these last, the tenderer of the two, may fall upon them instead of the others, as they never fail to do. There are three forts of Artichoaks, viz. the green, or otherwife white ones, which are the most early: the violet ones, whose Fruit is almost of a Pyramidal figure, and the red ones, which are round and flat like the white ones; the two last forts are the most delicious.

ASPARAGUS are fown at the beginning of the Spring, like other Seeds; that is, they are fown on fome Bed well prepared; they must be sown indifferent thin; sometimes these Seeds are sown in the Shell as they grow, that is, four or fix Seeds in a Shell, but the best way is to break them, and beat the Seed out of them; the time of fowing them is about the latter end of March; about a Year after, if they are big enough, as they will be if the Ground be good, and well prepared, or if not, at least at two Years end, we must transplant them, which is to be done at the end of March, and all the Month of April; and to this purpose we must have Beds between three and four Foot broad, and seperate one from the other: If it be in ordinary Ground, we dig these Beds hollow with a Spade, throwing up the Earth that is taken out of them upon the Path-ways; and as to ftrong, heavy and moift Grounds, I would have them thus order'd; that is to fay, I would have the Beds in them not at all laid hollow, but on the contrary raifed and kept higher than the Path-way, too much wet being mortal to these Plants. Asparagus being thus sown, shoot out Tufts of Roots round about their Eye, or Mother-Root, that isto fay, round the placefrom whence all their Shoots are to fpring; which Roots spread between two Earths; and in order to transplant them either into a hollow Bed, or a high-raifed Bed, we heltow a good thorough Tillage on the bottom of the Trench, and if the Ground be not very good, we dung it a little, and afterwards we plant two or three

Vol. II. The Compleat Gard'ner. 179

Stocks of these young Plants, orderly in Ranks, upon the superficies of the Beds prepared for them, without needing to trim the extremity of their Roots, or at least but a very little; and if our Intention be to force this Asparagus by an artificial Heat, when they are grown big enough, we place them at a foot distance one from another; and if they be to remain to grow after the usual manner, we allow them a foot and a half distance; but in both cases we place them checker-wife, and when they are fo placed, we cover them up again with two or three Inches deep of Earth: If any of them fail to spring up, we may renew them two or three Months after; which is to be done in the fame manner as we planted the others only taking care to water the new-planted ones during the great Heat, and to keep them always well weeded and well dung'd about; or elfe we mark out with little Sticks the empty places, and stay till the Spring before we fill them up again.

Every Year we cover the Bed with a little Earth taken off from the Path-way, because instead of sinking, they always are rising by little and little; we dung them moderately every two years, and let them shoot up three or four Years without gathering any, 'till we see them begin to grow pretty thick, and then we may force as many as we please of them; or if not, we continue to gather of them every Year a Crop, for sisteen Years, before we need to renew

them.

Every Year, about Martlemas, we cut down all their Stems, every Steck producing feveral Stems, and take the fairest of them for Seed; if we would have them come to bear, we must use an Iron Fork to draw them out of the Nursery-Beds, the Spade being dangerous for that work, because it would cut and hurt those little Plants.

We must not fail every Year, at the latter end of March, or beginning of April, that is, before the Aspa-

ragus begin to sprout naturally, to bestow a small dreffing or stirring of the Ground about three or four Inches deep on every Bed, taking care not to let the Spade go fo deep, as to hurt the Plants; which fmall Dreffing ferves both to kill the Weeds, and to render the superficies of the Earth loofe, and thereby not only the better to dispose it to drink up the Rain, and the May-Dew that nourishes the Stocks, but likewise to facilitate the Passage of the Asparagus in sprouting.

The particular and most dreadful Enemies of Asparagus are a fort of Fleas that fasten upon their Shoots. and make them miscarry, and hinder them from thriving; they are most troublesom in very hot and dry Weather: There has been no Remedy found yet a-

gainst this mischief.

B

BALM, called in French Melesse, is an odoriferous Herb, whose Leaf, when tender, makes a part of Sallad-Furnitures; it is multiplied both by Seed and rooted Branches, like Lavender, Thyme, Hys-

fop, 8tc.

BASIL, or Bafilick, as well the great fort as the small, is multiplied by Seed, which is of a blackish Cinnamon Colour, very fmall, and a little oval, it's propagated only by Seed; it is annual, and very delicate, we feldom fow it but upon Hot-beds, and not in open Ground, as we do Purstain, Lettuce, &c. We begin to fow fome in that manner, at the beginning of February and we continue so to do the whole year; its tender Leaves are us'd in a small quantity, with the Furnitures of Sallads, among which they make an agreeable Perfume; it is likewise used in Ragous, especially dry ones, for which reason we take care to keep some for Winter. We gather its Seed in the Month of August, and usually to make it run to Seed,

we transplant it in the Month of May, either in Pots or Beds; there are several forts of it, but that which bears the biggest Leaves, and especially if they encline to a Violet Colour, and that which bears the least Leaves of the two is the most curious; that which bears middling ones being the ordinary or common fort.

The Common B A YS, is a Shrub of no very great use in our Gardens and therefore it is enough to have some fewPlants of it in some well shelter'd place to gather some Leaves of them when occasion re-

quires.

BEANS, as well the common, and Garden-Beans, as those called Kidney-Beans, and French-Beans, and in French, Aricos, are sown in open Ground, and grow not otherwise; the Arico, French, or Kidney-Beans, are sown the latter end of April, and all the Month of May, and are very sensible of the Frosts; the common Garden-Beans are sown at the same time with Hastings Pease; both in November and

February.

BEET-RAVES, or Beet-Radishes, that is Red Beets, produce Roots for Sallads, and are multiplied only by Seed, which are about the bigness of a middling Pea, and round, but all rough in their roundness; they are yellowish, and so like those of the white Beet, that they are hardly to be diffinguished one from the other; so that People are often mistaken, thinking they have fown red ones for Roots, and fee nothing come up but white Beets! they are fown in the Month of March, either in Beds or Borders. They must be fown very thin, or at least, if they come up too thick, they must be very much thin'd, or else they will not grow fo fair and fo large as they should be. They require a very good and well-prepar'd Ground; they are the best that have the reddish substance and the reddest tops, they are not good to spend till toward the latter end of Autumn, and all the Winter-

O 2 Seafon

182 The Compleat Gard'ner. Vol. II.

Season: To have Seed of them, we transplant in March some of the last Years Roots that we have preferved from Frost; their Seed is gathered in the Months of August and September.

BEET-WHITE, called Porce or Poirce, are also propagated for Chards by Seed only, which is like that of the red Beets, but that 'tis of a duller Colour, they are replanted to produce Chards. Vide Chards.

BONNE Dame, or good Lady, is multiplied only by Seed, which is extreamly flat and thin, round and

reddish.

BORAGE is propagated only by Seed, which is black and of a long, bunchy, oval figure, having commonly a little white end toward the Base or Bottom, which is quite separated from the rest; the length is all engraven as it were with black Streaks, from one end to the other. It grows like, and is to be ordered in the same manner as Arach, only it comes not up so. vigoroufly: We fow feveral times in the Summer, because the Leaves, in which confists all its Excellence, are good only while they are tender, that is, while they are young; the Flowers ferve to adorn Sallads; the Seed falls as foon as ripe, and therefore must be carefully watched; the furest way is to cut down the Stalks, and lay them a drying in the Sun, as foon as ever they begin to ripen, and by that means we shall lose but very few.

BUGLOSS is likewise multiplied only by Seed, and is so like that of Borage, that they cannot be known asunder; and are likewise to be ordered as-

ter the fame manner.

BUCKS-HORN Sallad is multiplied only by Seed, which is one of the leaft we have; it is longish, of a very dark Cinamon Colour, and grows in a Husk like Rats Tail. Vide Harts-Horn Sallad.

EURNET is propagated only by Seed, which is pretty big, and a little oval, with four fides, and is all over engraven, as it were, in the spaces between those four

fides ;

Vol. II. The Compleat Gardiner. 183

Sides: 'tis a very common and ordinary Sallad-furniture, which is feldom fown but in the Spring, and is fown thick either in Beds or Borders; it often forings afresh after cutting, of which the youngest Shoots must be chosen for Sallads, the Leaves that are any thing old being too tough; it does it a great deal of good to water it in Summer: There is but one fort of it, whose Seed is gathered at the end of Summer.

CABBAGES, called in French, Choux, and comprehending both Cabbage, Coleworts, and Colly-flowers of al! kinds, of what nature foever they be, are multiplied only by Seed, which is about the bigness of an ordinary Pin, or of Birding Powder, and is reddish, inclining

to a brown cinnamon colour.

CABBAGES, of all forts of Kitchin-plants, take root again the eafiliest when transplanred, as they are likewife the most known, and most used of any in our Gardens; they are multiplied by Seed, and are of feveral forts and Seafons; there are some called White Headed Cabbages, which are for the latter end of Summer, and for Autumn; there are some curled, called Pancaliers, or Millan Cabbages, which produce small-headed Cabbages, for Winter; there are some of a red or violet Colour; and fome called long-fided Cabbages, whereof fome are bright or white, and very delicate, ripe in vintage-time; and others green, and are not very good till they are frost-bitten: Lastly, There are some call'dColly-flowers, which are the most noble and valuable of them all, and are not used in Pottage, but in choice Intermesses; they cannot endure the Frost, and therefore as foon as they begin to form their Heads, they must be covered, with their Leaves ty'd up for that end over them with Straw-bands, to guard them from the infults of the Cold, that spoils and rots them; they are for our Winter spending, and must be sheltered in

184 The Compleat Gard'ner. Vol. II.

the Green-House or Conservatory, whither they must be carried and planted with a Turf of their old Earth about them, where they are commonly used to perfect the full growth of their heads: All other Cabbages yeild Seed in France, but only these, whose Seed we are sain to have brought up from the Eastern Countries, which makes them ordinarily very dear. To make Cabbiges run to Seed, we use every Year, either in Autumn or Spring, to transplant some of the best and fairest of them, which run to Seed in the Months of May and June, and is gathered July or August.

CAPUCIN Capers. See Nasturces.

CAPUCIN CAPERS, or Nasturces, are annual Plants, which are usually fown in hot Beds in the Month of March, and transplanted again in the naked Earth along by some Walls, or at the foot of some Trees, where their mounting Stalks, which are but weak and grow pretty high, may take fome hold to fupport themselves: They are also planted in Pots, and Boxes, in which some Sticks are set up to support their Stalks; their Buttons or round Buds before they open are good to pickle in Vineger; their Flower is pretty large, of an Orange Colour, and very agreeable: They must be carefully watered in the Summer, to make them shoot vigorously. Their Seed falls to the Earth as foon as ever it is ripe, as well as that of Borage and Bugloss, and therefore must be carefully gathered up.

CAPRONS. See Straberries.

CARDONS Spanish, are propagated only by Seed, which is longish, oval, and about the bigness of a fair Wheat-Corn; it is of a greenish, or Olive Colour, mark'd with black Streaks from one end to the other, and is sown from the middle of April, to the end

They grow naturally from Seed, and are fown at two feveral times; the first is commonly about

Vol. II. The Compleat Gard'ner. 185

the middle or latter end of April; and the fecond about the latter end of May. They must be sown in good and well-prepared Ground, and in little Trench. es, or Pits, a full Foot wide, and about fix Inches deep, fill'd with Mold; we make Beds of four or five Foot wide, in order to place in them two ranks of those little Trenches, or Pits, chequer-wise; we put five or fix Seeds in every hole, with intention to let but two or three of them to grow; if they all come up, taking away all those that are over and above that number, either to throw away, or to new stock those places, where perhaps are none come up, or where perhaps we may have fown but fome few upon a bot-Bed for that intention; and if in fifteen or twenty Days we do not see the Seed come up, we should uncover them, to fee whether they be rotton, or begin to fprout, that so we may fill up their places with new ones, in case of need. The Seeds of the first Sowing are generally three Weeks coming up; and those of the second fifteen Days: Cardons must not be fown before the middle of April, for fear they should grow too big, and run to Seed in August and September, and then they are not good: Great care must be taken to water them well; and when towards the end of October, we have a mind to whiten them, we take the advantage of a dry Day, first to tie up all their Leaves with two or three Bands, and some days after, we cover them quite up with Straw, or dry Litter well twifted about them, fo that the Air cannot penetrate to come at them, except it be at the very top, which we leave open.

These Cardoon Plants, thus wrapt up, whiten in about fifteen Days or three Weeks, and grow fit to eat; we make an end of tying up, and wrapping or covering all we have in our Gardens, when we perceive the Winter approach, and then we take them up with the Earth about them, to transplant them into our Green-House or Conservatory; some of those Plants

are good to transplant in the naked Earth in the following Spring, to run to Seed in Fune or Fuly; or else some Plants of them tied up in their first places, will

ferve for that three or four times together.

CAROTS are multiplied only by Seeds, which are finall and oval, the fides of which are wrought with little Streaks, or longish Points very finall; and one fide of the flat part of the Seed is a little fuller, and more raised than the other; and both of them are marked longwise with Strakes; they are of the colour of a dead Lease; are a fort of Root, whereof some are white, ond others yellow, that grow only from Seed, and require the same care and ordering, which we have already described under the Head of Red-Beet-Roots.

CELLERY is multiplied only by Seed, which is very finall, yellowish, and of a longish oval figure, and a little bunched; it is not good but at the end of Autumn, and during the Winter-Seasons; we fow of it two feveral times, to be fupply'd with it fomuch the longer; that which has been long fown, eafily runs to Seed, and grows hard: We fow it then the first time in bot-Beds in the begining of April, and because its Seed is so extreame small, we cannot help sowing it too thick: So that if we be not careful to thin it, and crop it in time, to make it grow to some strength and bigness before we transplant it, it warps and flags its Head too much, and grows weak, and shoots its Leaves stranglingly outward, instead of producing store of them from the middle of its Stock: The surest way to transplant it in a Nursery-Bed, is placing the Plants two or three Inches from one another; for which we make holes with our Fingers only; we transplant that which comes of the first sowing at the beginning of June, and fow our fecond fowing the latter end of May, or beginning of June; but it is in open beds, and we take the same care to thin, crop, and transplant this, as we did that of the first sowing?

but

Vol. II. The Compleat Gard'ner. 187

but we must plant more of it the second time, than at the first. There are two ways of transplanting it, the one is in a Pit or Trench a full Spit deep, and between three or four foot broad, in order to place in it three or four ranks of those Plants, at the distance of one foot from one another; this way of making hollow-beds to earth up our Cellery in, is good only in dry Grounds wet Grounds being too apt to rot them. The second way of transplanting it, is in plain Beds, not made hollow, and at the same distance as the other taking care in both forts of Beds, to water them extremely in the Summer-time, its chief goodness confifting in being tender, as well as in being very white; watering contributes to the first kind of goodness, and for the fecond, you are to observe, that to whiten Cellery, we begin at first to tie it with two Bands when it is big enough, chufing dry Weather for that effect, and afterward we earth our Cellery Plants quite up, with Earth taken from the high-raifed Path-ways, or else cover it all over with dry long Dung, or dry Leaves, as we do Cardoons. Cellery, fo earthed up with dry Earth or cloathed with long dry Dung, or dry Leaves, to the very tops of its Leaves, whitens in three Weeks or a Month; and because when 'tis whitened, it rots as it stands if it be not presently eaten, by confequence we are not to earth it up, or cover it with Dung, but in fuch proportion as we are able to spend out of hand. There needs no other Precaution to be used in it, so long as it does not freeze; but as soon as ever it begins to freeze, we must then quite cover up our Cellery all over, for a hard Frost spoils it presently; and that we may the more easily cover it, after we have first ty'd it up with two or three Bands, we take it up with the Earth about it, at the beginning of Winter, and plant it in another Bed, fetting the Plants as close as we can to one another, and then there needs much less stuff to cover them than when they are left standing in their old

old places at such great distances a sunder. The way to raise Seed from them, is, to transplant some Plants of them in some bye-place, after Winter is past, which will not fail to run to Seed in the Month of August; we know but one sort of it.

CHARDS of Artichoakes. See Artichoks.

CHARDS of Artichoks, otherwise called Costons, are the Leaves of fair Artichoke-plants tied, and wrapt up in Straw in Autumn and Winter; which being covered up all over, but at the very top, with Straw, grow white, and by that means lose a little of their Bitterness; so that when they are boiled, they are served up like true Spanish Chadrons, but after all, are not so good, and besides the Plants often rot and perish, whilst we are whiting them

CHARDS-BEET. See Beet.

CHARDS of Beets, are Plants of white Beets transplanted in a well-prepared Bed at the distance of a full Foot one from the other, which produce great Tops, that in the middle have a large, white and thick downy, Cotton-like main-Shoot, and that Cotton-like Shoot is the true Chard used in Pottages and Intermesfes: After we have fown white Beets upon hot-Beds, or in the naked Earth, in the Month of March, we transplant that which is yellowest, in Beds purposely prepared, and by taking care to water them well in the Summer, they grow big and strong enough to refist the hard Winter Cold, provided care be taken to cover them with long dry Dung, just as we do Artichokes: They are likewise well placed, when two Ranks of them are planted between two Ranks of Artichokes; we uncover them in April, and dress the Earth about them, and give them careful attendance, and by the means of this diligent Culture, they produce those fine Chards we have in the Rogation Season, and in the Months of May and June. In fine, they run to Seed, which we gather in the Months of July and August, and sow in the following Spring. CHERVIL

CHERVIL is multiplied only by Seed, which is black, very finall, and pretty longish strip'd, longwise; it grows upon Plants that were fown the Autumn before and knits and ripens in the Month of June.

Musked Chervil is only multiplied by Seed, which is longish, black, and pretty big; it is one of our Sallad Furnitures; and at the beginning of the Spring, whilst its Leaves are young and tender, it is agreeable, and proper to contribute towards the giving a persuming relish; but it is to be used no longer when they are old and tough: it remains several Years in its place without being spoiled by the Frost, so that its Stock grows pretty big and high; it runs to Seed towards the Month of Tune, and by that is multiplied.

Ordinary Chervil is an annual Plant, or rather a Plant of few Months, which ferves for many uses, and especially in Sallads, when it is young and tender; and therefore we ought to sow a little of it every Month, proportionably to the occasion we may have for it, and to the quantity of Ground we have; it runs very easily to Seed, and if we have some of it betimes, we must sow it by the end of Autumn, and doubtless we shall have the Seed quite ripe towards the middle of June following; we cut down the Stalkes as soon as it begins to grow yellow, and beat it out, as we do that of other Plants.

CIBOULES, or Small Onions, are propagated only by Seeds of the bigness of a Corn of ordinary Gun-powder, a little flat on one fide, and half round on the orher, and yet a little long and oval, and white on the infide, so like to which are both the Seed of the red and white Onion, and of Leeks, that it is very hard to distinguish them one from another. Ciboules

are fown in all Seafons.

Ciboules, or Chibouls, properly speaking, are but Onions that are degenerated, and of which Nature has as it were miscarried, that istosay, Onions that instead of producing

190 The Compleat Gard'ner. Vol. II.

a little Root in the Earth, and one single Stem, produces but a small Root, and several Stems, or upright Shoots, and those which produce most of them are most esteemed, which are the fort of which we should be careful to preserve most Seed, and which, if planted in March will yield us Seeds fit to gather in August. We fow Cibouls almost in every Month in the Year, except in very hard Weather, when the Earth cannot be cultivated their Seed are so perfectly like that of Onions, that they cannot be diffinguish'd one from the other; but the former never recover fo as to produce Onions, and particularly those we pluck up out of the Onion-Beds, which are fown too thick, and must be thin'd that those which are left, may grow the bigger; we thin our Cibouls also for the same reason, and we transplant fome which prosper very well, and grow big when they are transplanted. It is convenient to water our Ciboul-Beds in Summers that prove extraordinary dry; and unless in such cases, they will not need watering, but however they must be always planted in good Earth.

CITRULLS, Pumpions, or Pumkins, are propagated only by Seeds, which are of a flat and oval figure, and pretty large and whitish, and are as it were neatly edged about the sides, excepting only at the bottom, where they stuck to the Citrull, in whose Belly they

were formed.

They are the biggest Productions which the Earth brings forth in our Climates, for whose Culture little is to be done: Usually we sow them in hot Beds about the middle of March, as the only way to preserve and multiply them; at the end of April we take them up with the Earth about them, to transplant them in holes made for that purpose, of about two Foot diameter, and one Foot deep, and two Fathoms distant one from the other, which are filled with Mould; when their Vines begin to grow five or six soot long, which happens about the beginning of Fune, we throw upon them

them in the middle of that length, fome Shovels full of Earth, both to prevent their being broken by the Wind's blowing them to and fro, and to make them take root at the place so covered; by which means, the Fruit that grows beyond that part will be the better nourished, and consequently grow the bigger. There are two forts of Pumpions, the Green, and Whitish, but neither of them are fit to be gathered till they be grown Yellow, and the Skin become tough enough to refift one's Nail; we keep of them in our Store-houfes till about the middle of Lent, when they have been feafonably gather'd, and well defended from the Cold.

All forts of Situations in the open Air agree with them well enough, but those which are well expos'd ripen foonest; we trim nothing off from them, but only content our felves with watering them fometimes, when the Summer is excessive dry; their Seed

is in their Bellies.

CIVES, or English Cives, are multiplied only by Off-sets that grow round about their Tuffts, which grow very big in time, from which a part are taken to replant: They are multiplied by producing thick Tuffts, which are flipt out and seperated into many little ones, and are transplanted nine or ten Inches afunder, either in Borders or Beds; they require pretty good Ground, with which if they be accommodated, they will last three or four Years without removing, without needing any great Culture, it being enough to keep them well weeded, and to water them fometimes during the Heat; it is their Leaves only that are used for one of the Sallad Furnitures.

COLLY-FLOWERS. See Cabbage.

COLWORTS. See Cabbage.

CRESSES, called Alenois Cresses, are multiplied only by Seed, which is of a longish oval figure, small and of an Orange vellow Colour.

192 The Compleat Gard'ner. Vol. II.

Garden-Cresses are one of the little Sallad-Furnitures, and is a Plant that lasts but a little while; we sow it every Month as we do Chervil, that we may always have some of it that is tender, and we sow it always very thick; it is propagated only by Seed, which is very apt to run, and which we begin to gather at the end of June, cutting down the Stalks in order to dry them, and beat out the Seeds and winnow them as we do those of other Plants, as soon as

we perceive any of them to ripen.

CUCUMBERS, or Coucumbers, are propagated only by Seed, which is oval, a little pointed at both ends, but a little less at the lower end or bottom than at the other, out of which springs its Bud or Sprout; it is of a midling Thickness of a whitish Colour, and is gather'd out of the Bellies of those Coucombers that are grown yellow with ripness. See their Cuiture, under the Head of Mellons, and Musk-Mellons. It is to be observed, That a Cucumber Plant yeilds a great quantity of Fruit, and for a long time when 'tis well cultivated, and especially when it is well watered.

CURRAN-BUSHES, whose Fruit grows in Bunches, both the red and the white, called Dutch Currans; as also Goose-berry Bushes, called in French, Groseilles, or prickly Grosseilles, are multiplied as well by Slips that are a little rooted, that sprout out at the foot of their Stocks, every Year, in the Spring, as by simple Cuttings; we also replant their Stocks

of two or three Years old.

CURRANS, and Goofe-berries, being both comprehended under the French name Grofeilles, both the red and the white or pearled fort, termed in English, Currans, and the prickly fort, called in English, Dutch Goofe-berries, are kinds of little Fruit-shrubs, which yeild a great deal of Fruit; they produce round about their old Stock, a great number of rooted Suckers or Slips, which serve to propagate them, besides which

their

their Branches, and especially the young ones that are cut off from them, take root easily; they are planted in the Month of March, at the distance of at least fix good Foot one from the other either in whole Beds or Squares, or in the void spaces between the Dwarf-Trees, which are usually planted about the Squares of Kuchen or Fruit-Gardens; both of them delight in a Ground that is a little moist, the better to enable them to produce

thick Shoots, and confequently good Fruit.

The red, and pearled or white fort, called in English, Currans, produce Bunches, which are ripe in July, but the prickly ones, named in English, Goofe-berries, produce none, but bear their Fruit upon fingle Stalks all along the young Branches of the preceding Year's growth, and that at the place of every one of the Eyes or Buds of that Branch; the Fruit of this latter is used particularly in April and May, in Compotes, and wet Sweet-Meats, and Sauces, for which uses it must be very green; for when it is ripe, it grows too foft and flat: The Culture that is most proper to be used for both Currans and Goofe-berries, and especially to Currans, confifts in cutting away all the old Wood, and preserving only that of one or two Years growth; for a confused mixture of one with the other, is not only very difagreeable and pernicious, but the old Branches will bear nothing but very small Fruit, till at last they quite degenerate, fo that they will bear none but fmall, common, and very four Currans or Goofeberries, and as foon as the old Stocks have done bearing any longer either fair Branches or good Fruit, we should take a resolution utterly to grub them up, after we have first raised a Plantation of new ones in fome other choice fresh piece of Ground, to supply their places; for a Garden ought by no means to be without fair Currans and Goofe-berries, and as foon as ever the new ones begin to bear, we are to deftrov the old ones, which make but a very unlightly figure in a Garden.

DOCK-

T

DOCK, called Patience, being a fort of Sorrel, is multiplied only by Seed, which is like Sorrel-feed, only a little bigger; properly speaking, it is but a fort of very great or large Sorrel, which is very sowre; we content our selves only with some Borders, or perhaps some one single Bed of it, to have some of its Leaves, to mix now and then among our Sorrel: The manner of raising it, is the same we practise with Sorrel.

E

ENDIVEWHITE, called in French, Chicorce i.e. Succery, is multiplied only by Seed, which is longifh, of a whitish-gray colour, flat at one end, and round-ish at the other, and grows upon the Stocks or Stems of the preceding Year's growth, one wou'd take it almost

for nothing but little bits of Herbs cut small.

ENDIVE-WILD, or Succery, is also propagated only by Seed, which is longish, and blackish, and grows as the other doth: It is a fort of very good annual Plant, used in Sallads, and in Pottage in the Autumn and Winter Seasons, provided it be well whitened, and consequently tender and delicate; it is multiplied only by Seed. There is the common or Garden Endive, and Wild Endive, called also Succery, the common Name in French to them both. The common Endive is of several kinds, viz. the white, which is the most delicate; and the green fort, which is most rustical, and best able to resist the Cold; as likewise the curled fort, and that which is not curled.

All forts of them agree tolerably well with all kinds of Ground; we feldom begin to fow any of them till towards the middle of May, and then they must be fown very thin, or be very much thin'd afterwards.

in order to be whitened in the places where they first grow, without transplanting, and we also sow but a little quantity of them at once, because they are apt to run to Seed: The feafon of fowing a greater quantity of them, is about the latter end of Fune, and during the whole Month of July, in order to have some good to spend in September; and we afterwards fow a great deal of it again in August, that we may have a fufficient quantity of it, to serve us all the rest of Autumn, and the first part of Winter; and when our Endive comes up too thick, we cut it, or else pull up some of it, to thin it, that the rest may grow big enough to be transplanted; and when we transplant it, in Summer-time, it must be placed at the distance of a large Foot between Plant and Plant; we usually make great Beds of five or fix Foot broad, in order to plant them afterward in it, in Lines marked out with a Cord. This Plant requires great and frequent Waterings, and when it is big enough, we mult go to work to whiten it; for which effect we tie it up with two or three Bands, according as its height requires; and being so tied, it whitens in fifteen or twenty Days: But because it is very apprehensive of Frost, therefore as foon as ever the Cold begins to come on, we cover it with long dry Dung, whether it be tied up or no: at the end of September we plant the Stocks of it pretty near together, because then it neither grows fo high, nor spreads so much as in Summer; and if we can fave any Plants of it in Winter, we must transplant them again in the Spring, in order to produce Seed that may have fufficient time to ripen. Those Perfons who have a good Confervatory or Green-House, will do well to house it up their; but they who have none, must be content to cover it up with a good quantity of long dry Dung, so that the Frost may not come at it.

WILD ENDIVE, or Succory, is fown at the beginning of March, and that pretty thick, and in Ground

196 The Compleat Gard'ner. Vol. II.

well prepared; we endeavour to fortifie it, and make it grow big all Summer, by watering and cropping it,

that it may be fit to whiten in Winter.

There are some People that will eat it green in Sallads, though it be never fo bitter; but commonly they rather defire it whiten'd; and to whiten it, we cover it up with a great deal of long Dung, after we have first cut it close to the Earth; by which means it being fotc'd to fpring up in obscurity, and shaded from all Light, its young Shoots grow white and tender. The nearest way is by interposition of some props crossing from fide to fide, to keep the Dung from touching it. fince it shoots up in the same manner under such a hollow covering, as under a close one: so that care be taken fo well to frop up Paffages on all fides, that no Light or Air at all get in; being thus order'd, its Shoots are much cleanlier, and relish not so much of the Dung. They which have Conservatories, may transplant some of it thither in Winter, it sprouting well enough there, when it is but a little obscurely plac'd: when it is green it endures the Frost well enough, and at the very latter end of May it runs to Seed. Many People eat its Shoots in Sallads, when they are young and tender

F

FENNEL is propagated only by Seed, which is pretty fmall, longish, and oval, bunched, and streaked

with greenish gray Streaks.

Tis one of our Sallad Furnitures, which grows only from Seeds, and is feldom transplanted; it resists the Cold of Winter: We sow either in Beds or Borders, it springs again when cut; its youngest and tenderest Shoots are the best: The Seed is garhered in August; and, in fine, it agrees well enough with all forts of Grounds. See more of it under Anis.

G

GARLICK is produced by a kind of Kernels, or Offsets, which grow in great numbers about its Foot, and make altogether a kind of Bulb like an Onion, which Kernels are called the Cloves of the Garlick, every Clove being concave or hollow on the infide, and convex or bending outward on the outfide, having at its lower end a flat Base or Bottom, by which it is fastened to the Foot or Stalk, out of which the Roots ipring; and having on the Top a pointed end, out of which springs its Bud or Shoot, when it is planted in the Earth in the Months of March or April, in order to its bringing forth.

It's propagated by Heads or Kernels called Cloves, about the end of February, which are fet three or four Inches deep in the Ground, and at three or four Inches distance one from the other; they are taken out of the Earth at the end of Fuly, and laid to dry in a place free from moisture, in order to preserve them from one

Year to another.

GOOSEBERRIES. See Currans.

H

HYSOP, or HYSOPE, is propagated only by

Slips.

HARTS-HORN, or Bucks born Sallad, is a little annual Plant, whose Leaves, when tender, are used in Sallad Furnitures; they are sown in March, very thick, it being impossible to sow them thin, because their Seeds are so very small, which are gather'd in August. The little Birds are very greedy of them, as indeed they are of all other small Kitchen-Plant Seeds: When the Leaves of this Plant are cut, there spring up fresh ones, just as there do also from Sorrel, Cives, Parsley, &c.

P 3 LAVEN-

LAVENDER is multiplied by Seed, and by old

Stocks or Plants transplanted.

It serves to garnish Borders in Kitchen-Gardens, and veilds a Flower, which, without being separated from its Stalk, is used to be put among clean Linnen, to perfume it; it is multiplied both by Seed, and by irs Branches or Slips which have taken Root at their Toints.

LAWREL. See Bays.

LEEKS are multiplied only by Seed, which is altogether like that of Ciboules; they are replanted in May, very deep in the Earth, to make their Stalks and Plants thick and white; and they are fown in March, as foon as the Frost will permit their Seed grows in a kind of thick white Purfe, which is round, and grows upon the top of a good long Stalk, and it keeps a pretty long time in that Purse or Hood before it falls.

They are fown at the end of Winter, and that pretty thick, in Beds well prepared; after which, during the whole Month of June, take them up neatly, and transplant them into other Beds which are no less carefully prepared; in order to which, we make with a planting Stick, holes about four Inches deep, and half a Foot asunder, and after we have a little trim'd both their Roots and Leaves, we only slide down a fingle Plant into every hole, without minding to press down the Earth about it, as we do to all other Plants; however, we take care to grub up the Weeds about them, from time to time, and to water them a little in very dry Weather, that their Stem may grow to a due thickness, and may whiten before Winter: when the Frost is very brisk, it is best to cover them, or else to set them in Earth in the Confervatory; it is likewife very convenient to take them up out of their Bed where they are planted a little at large, and to place them nearer together afterward in another Nurfery-Bed, and cover them up with long Litter, because otherwise when it freezes hard, we should not be able to get them out of the Ground without breaking them; we may leave some of them standing, after Winter, to run to Seed, or else we may plant some of them in a separate place for that purpose; their Seed is gather'd in August, and there is a fort that is bigger than the ordinary one, which is the best.

LETTUCES, of what fort foever they be, are multiplied only by Seed, which is of a longish oval figure, streak'd longish, sharp pointed at the end, and very small; some are black, as those of Aubervilliers, but most of them are white: when they are sown in the Spring, they run to Seed in July after: But the Winter Lettuces, called otherwise Shell-Lettuces, after having pass'd the Winter in the place where they were replanted in October; run up to Seed in July

following.

They are Plants that are the most ordinarily and commonly feen in our Kitchin-Gardens, and are inneed the most useful Manna of them, and especially for Sallads, of which almost all Mankind are defirous we have many kinds; for in the first place, there are Lettuces of different Seasons; those which are good in certain Months of the Year, being not good in others; and those which grow well in the Spring, not thriving in the Summer; and they which prosper in Autumn and Winter, coming to nothing neither in Spring nor Summer, as will be feen afterwards. In the Second place, There are some that with the ordinary help of the general Culture attain their due Pertestion, and contribute both to the Nourithment and Pleasure of Mankind, and they are the Cabbage Lettuces. Thirdly, There are some that necessarily require the Art and Industry of the Gard'ner, to advance

them to that degree of perfection which they should have; and they are such as must be tied up, to make them grow white, without which they would be neither tender, nor fweet, nor good; fuch as are the Roman Lettuces, &c. nay, and I have thought fit fometimes to tieup those that were to cabbage, when I saw they did not cabbage foon enough, by which means they may be forced to cabbage: I use this method particularly with some forts of Winter Lettuces, that is, when there are any of them, which though furnished with Leaves big enough to cabbage, yet for want of fufficient Heat, are hinder'd from turning, that is, from growing hard; and this Expedient is a very fovereign Remedy against that defect, in a furly Season: And besides these general distinctions, the number of the particular kinds of Lettuces is greater than of any other fort of Kitchen-Plants whatfoever, as will appear more especially by the order they observe in respect of the Seafons. And the order of the Cabbage Lettu-

ces, as near as I can describe, is this:

The first that cabbage at the going out of Winter, are the Shell-Lettuces, so called because their Leaf is round almost like a Shell: They are otherwise called Winter-Lettuces, because they pretty well endure ordinary Frosts, which none of all the other Lettuces can do; these are sown in September, and afterwards transplanted in some Wall-border towards the South and East, in the Months of October and November; or else they are fown upon Hot-Beds, under Bells, in the Months of February and March, and are good to eat in April or May. We have at the fame time another fort of reddish-Lettuces, called Passion-Lettuces, which prosper very well in light Grounds, but not over well in athers, which being colder, but stronger or heavier, cafily infect them with flimy Snivel: both these kinds should, when they thrive, produce very thick and good Fleads. To these succeed the bright curled Lettuces, which usually cabbage in the Spring, that is, be-

fore the Heat grows any thing excessive, but they must not be planted in strong heavy Lands: they likewise do well upon Hot-Beds, and especially under Bell-Glaffes, or Glass Frames; for when they are sown in Fanuary, and transplanted as soon as they are grown any thing thick, or else left thin upon their Nursery-Beds, they cabbage as foon as the Winter Lettuces, and are very excellent.

There is about the fame Seafon, two other forts of bright curled Lettuces, viz. one called George Lettuces. which are thicker and less curled than the ordinary bright curled Lettuces; and other called Minion Lettuces, which is the least fort: both these last require fuch Ground as we term good black Sand, but yet their Heads are feldom cabbag'd close enough, that is to fay, are not ordinarily fo hard and firm as those of the right curled bright Lettuces.

The curled green Lettuces come in near about the fame Seafon with the preceding ones, but are not for

tender nor delicate.

There is also a fort of small red ones, and another named short Lettuces, both which have all the necessary Qualifications of good Lettuces, excepting only that their Heads are small, and that they likewise re-

quire black fandy Ground.

The first Lettuces supply us amply, as I have said, during April and May, and the begining of June, but afterwards they are too apt to be enclin'd to run to Seed, by the great Heat that then comes on; they are follow'd, during the rest of Fune and all Fuly, by those called the Royal Bell-gards, or fair Looks, bright Genoa's, Capucins, Aubervilliers, and Perpignans, of which last there are both green and bright, both of which produce very fair and good Heads, and thrive well enough in strong Grounds too, when the Summer proves not too rainy; but Cold or too frequent Rains infect them with Slime and Snivel, and confequently destrov

202 The Compleat Gard'ner: Vol. II.

destroy them. The Cappucin Lettuce are reddish, cabbage easily, even without transplanting, and are pretty delicate; the Aubervilliers bring forth Heads that are too hard, and sometimes bitter withal, and are more used for boiling than for Sallads. The difference that appears between the Royal, and Bellgards of fair-look'd Lettuces, is only that the former look a little more greenish, and these last a little

brighter. However, in Summer-time, the tied Lettuces are mixed among the cabbage ones; viz. the Roman Lettuces, which are open, and are called Chicons, or bright, and are termed Alphanges, which last are more delicate than the Chicons, both to raife, and when they are eaten in Sallads: There are also a fort which are termed Imperial Lettuces, which are of an extraordinary Size, and are likewife delicate to the Tast, but very apt to run to Seed as soon as ever they grow white; there are besides a certain kind of large reddish Chicons, which whiten, in a manner, of themselves, without tying, and are good in course Grounds, and succeed usually pretty well in Summer; for as for the green Chicons, we cannot well have them but in the Spring, because they run too hastily to Seed: The Lettuces that defend themselves best from the great Heats that predominate about the end of Fuly, and all the Month of August, are those which we call Genoa Lettuces, and especially the green fort; for the bright Genoa and red Genoa run more eafily to feed, and will hardly come to good but in light Grounds; we should therefore prepare a great many of the green Genoa's against the Dog-Days, and the first Frosts; we may also intermix with them some few bright, and fome red Genoa's, but more especially we should be fure to mix with them some Alphanges, and a great deal of bright or white Endive, as likewife a great many Perpignan Lettuces, both of the

bright and green kind. The great Inconveniencies that happen to Cabbage Lettuces, are, fift, That they often degenerate so far as to cabbage no more, which is discovered by their Leaves growing out in length like a Car's Tongue, as the Gard'ners term it, or by changing their natural Colour into another more or less green; and therefore we must be careful to gather no Seed from any but fuch as cabbage very well: for which effect we should be very fure to mark out at first some of those that turn best, in order to reserve them to run to Seed where they stand, or to remove them with a Turf of Earth about them, into some separate place

affigned for that purpose.

The Second, is, That as foon as the most part of them are cabbaged, they must be spent, unless we would have the displeasure to have them run to feed. without doing us any fervice; in which respect, the Market Gard'ners have a great advantage beyond other Perfons, because they can fell off in one day whole Beds of these Cabbage Lettuces; for commonly the Beds which are new-planted at the same time, cabbage likewise all at once; whereas, in other Gardens, we cannot spend them any faster than we need them. for which reason we are oblig'd to plant some of them often, and that in greater quantity than we are able to confume, that we may have a continual fupply fucceifively, without any discontinuance, it being much more commodions to have an over.plus of them than'to want; the furest way is to keep particularly to those forts that are the most strong, and that last a great while cabbaged before they run to feed, fuch as are the Shell-Lettuces, the Perpignans, the great Genoa's, the Auber-villiers, and the Austrichettes, or Austrian Lettuces, which I must confess too are along time cabbaging.

The Third Reafon, is, That the Morie, which is the Rot, that begins at the ends of their Leaves, feizes

204 The Compleat Gard'ner: Vol. II.

them fometimes, and that when the Ground or the Seafon is not favourable unto them, they remain thin and lean, and run up to Seed instead of spreading and cabbaging. There is hardly any remedy to prevent this Rot, because there is hardly any to be found effectual against the cold and rainy Seasons that cause it; but against the defects that may be in the Ground, there are infallible ones, that is to fay, it must be amended and improved with small Dung, if it be barren, whether it be fandy, or a groß cold Earth; and to this last we should give a Slope, if when the Ground is good, the Water spoils it by standing too much upon it, and by that means make all the Plants growing there to rot: Good Dung throughly rotten being the Soul or Primum Mobile of Kitchen-Gardens, without which, no more than without frequent waterings and dreffing of the Ground, no Man can ever be richly

stor'd with fine and goodly Legumes.

There vet remains to be known, for the perfect understanding the ordering of Lettuces, that they which grow biggest must be placed ten or twelve Inches one from another, which is to be understood of the Shell-Lettuces, Perpignans, Austrians, Bell-gards, or Fair Looks, Aubervilliers, Alphanges, and Imperials; and for those that bear Heads but of a midling fize, the distance of seven or eight Inches is enough, which are the bright curled, the short, the little red, and the green Chicon Lettuces &c. Those that will be good Husbands, may fow Raddiffies in their Lettuce beds, because the Raddishes will be all drawn out and spent before the Lettuces cabbage; and for the same reason, because the Endives are much longer before they come to perfection than the Lettuces, we may plant some of these last among the Endives; they agree well enough one with another, and fo we may have a double Crop together upon the same Bed, and in the same Season; for the Lettuces are gather'd first, and afterwards the Endives arrive to their full Goodness.

MACHES,

MACHES, Masches or Corn-Sallads, are multiplied only by Seed, which is very small, and of an Orange Colour. They are a fort of little Sallad, which we may call a wild and rustical Sallad, because indeed it is seldom brought before any Noble Company; they are multiplied by Seed, which is gather'd in July, and are only used towards the end of Winter; we make Beds for them, which we sow about the end of August; they are hardy enough to resist the rigour of the Frost; and because they produce a great many little Seeds that easily fall though we have but a little quantity of them, they will propagate themselves sufficiently, without any other Culture but weeding them.

MALLOWS, or Marsh-Mallows, are propagated only by Seed, which are like one another in shape, but yet are different as well in Colour as in Bigness; for the Seed of the Mallows is much bigger than that of the Marsh-Mallows, and that of this latter are of a deeper brown than that of the plain Mallows; they are both

triangular, and streaked all over.

They ought to be allowed a place in our Kitchen-Gardens, though Civility will not permit us to explain in this Treatife what uses they serve for; and although they be Plants of the Fields, rather than of a Garden, they grow of their own accord, and have no more need of cultivating, than the Weeds which insess the good Plants, when we have a mind to have any of them in our Gardens, it will be best to sow them in some bye-place.

MARFORAM, is propagated only by Seed, which is very little, and shaped almost like a Lemmon, more pointed on the one side than on the other, it is speckled in some places with little white Specks, and as it were streaked with white all over:

266 The Compleat Gard'ner. Vol. II.

it is of a pretty light Cinnamon Colour, is an odoriferous Plant, of which we compose agreeable Borders and Edgings: There is the Winter-Marjoram, which is the best; and the Summer-Marjoram, which lasts not beyond the Season; both of them are multiplied by Seed, and likewise by rooted Slips or Suckers, they are principally used in making Persumes.

MELONS, or Musk-Melons, are multiplied by a Seed which is like that of a Coucumber, excepting in Colour, which in Melons is of a pale red, and is not fo broad as that of the others; they are taken out of the Bellies of the ripe Musk-Melons; of the Culture of which we shall here present you with a most ample Account, as it is has been delivered by the Ho-

nourable Mr. John Evelyn.

Directions

Directions concerning MELONS.

HE most undegenerating fort of Melons are not large, but of a middling fize, the Rhind thin, faintly embroider'd, and without being Ribb'd or divided along the Sides, or at least very obscure-" ly: Others there are which be whitish, some of a "Slate colour, Red-flesh, dry, yet melting in the Mouth, and not at all mealy, but of an high and " generous Gust. In a word, the only fort (after Trials of many hundred Kinds) I have Cultivated with Success, and that retain their good Qualities Alteration.

" more than Twenty Years, without any confiderable " Every Gard'ner now-a-days knows how to raife "Melons, but very few to govern them; the greatest eft difficulty whereof is in the Guelding of Super-"fluities, to cause them to knit, and bear as they " should do. In order to which, observe these few C Directions:

" The first thing appearing (after the Seed is fown, and the Plants prick'd out from the Hot-bed into " a more temperate) are a pair of small smooth " Leaves, which (in France) we call the Ears, " marked 1. 1. in the Figure. A few days after, "'twixt these, comes up a single Leaf, which we " call the first Leaf, as being on the First Knot, no-" ted 2. Next to this, in the same place, and soon " after, there appears another, which we term the " Second Knot, marked 3. About the middle of " whose Stalk there shoots out another Leaf, call'd " the Third Knot, figured 4. Which Third Knot " is always to be Pruned off at Fig. 6. but with " Care, and without wounding the Stalk or Branch " of the Second Knot, marked 3. upon which that "Third did grow; it being from this placeyou will " find that Branch to sprout, which we call the First " Leader; and is that which will fend out a First, " Second, and Third Knot; which Third (and all " other fuch Thirds) you must cut, or pinch off, as you did the other, without staying till a Fourth, " or Fifth, or more, shoot out. It is, I say, from " these Knots and Joints, that other Branches in like " manner will proceed, knit, and form into excellent "Fruit, provided the Foot and Original Stem have been " well nourished in rich, warm, and proper Mould, " and well expos'd. " I must not forget, that from the middle, like-

"wise 'twixt the Ears and two first Leaves, there frequently rises another Branch, which you may abate, or leave on, as you find it likely to prove, especially if a vigorous one; but the Least figured 5, issuing from the middle of the Fourth Joint, and several more besides, successively springing out of one another, as you see the Fourth from the Third (and as all the rest I have marked do) I purposely omit, and have only figur'd, as superfluous to the

" Ingenious Gard'ner.

"I commonly place two Roots together, unless I meet with an extraordinary good Plant, and then spare both the Branches which spring from each side, "twixt the Ear and Lease 7, 7, as before is shew'd: But when I Plant two Roots near each other (as I do when they are not very fair ones) I totally reject both Branches which shoot from the two opposities Ears, to avoid that Consusion of those Super-

"When I Transplant from this Nursery-bed (into the prepared Holes of Ridges, and open Meloniere)

" numeraries which injure the principal Stem and Foot

" it self.

"Never fuffer the Root, or Stalks of your Melon
"Plants, to touch the Dung; nor should you water
"them in immoderately, but when the Earth is very
"dry, and the Season excessively hot, refresh, and
"give the Roots Drink, without deferring it 'till the
"Shoots complain, when it may come too late: I
"water them in these parching Seasons, two or three
times every Week, and in the Evenings when the
"Sun is setting, and then cover them with Matras"ses, from Eleven 'till Two a Clock; and in the
"Afternoon during the Sun's excessive Violence,
"which exhausts and consumes the Humidity neces"fary to both Roots and Branches.

"I cover my Meloniere also when it rains, lest too much moisture prejudice the Fruit; all which requires a great deal of Care, and no small Pains, though this regular Proceeding is to me a real

· " Pleasure.

"When the Foot of your Melon-Plant grows over luxurious in Branches, cut away the feeblest of them, leaving not above three or four of the most vigorous, and whose Knots grow nearest to one another: And when the Melons are kint, suffer not above two upon each Foot, chusing such as are best plac'd, and nearest to the main and principal Stem, which should be thick, sing, and not too

Q,

210 The Compleat Gardner. Vol. II.

"far above the Ground. Of these that are knit, and "beginning to form, make choice of the handsomest that are well truss'd with a thick short Tail; Me"lons with long starts, slender and narrow Leaves,

" never prove worth any thing.

"When you begin to cover with Bells, raise them
"fo upon little Forks, as they neither rest upon the
"Fruit or Branches, or quite exclude the Air; but
"fo as to keep the edges from bruising, and pressing
"the tender Stalk, and Intercepting the Current

" Sap.

"It now and then happens, that there rifes a fe-" cond Branch from between the Ears, and two first " Leaves (though I mention'd indeed but one) but "this is very feldom; and you are still to count "then but for one Joint or Knot, though there will thence proceed a Second, Third, Fourth, and per-" haps Twenty of Thirty more, and further remote, " if you let them alone, and be not vigilant to re-" strain and stop his Exuberance in due time. 'Tis " true, they will prefent you with Fruit at the Extre-" mities of their Branches, but 'tis little worth, as being so far distant from the Root, that the Sap " spends it self in the tedious passage before it ar-" rives as you'll find by the withered Branch, and " driness of the Leaves which should skreen both " Branches, and Fruit 'till they are ripe, as we fee they do. where a Melon has a short and substantial " Foot. A curious Gard'ner therefore should visit his Meloniere from time to time, and be cutting off " all murilated, starv'd and vicious Branches which " annoy the Plants, for these Impertinents will grow even to the view of ones Eye, and quite impove-" rish the Fruit, if not timely prevented.
"Thus you see I am careful to purge the Stem of

"Thus you fee I am careful to purge the Stem of all the fmall, straggling, and unprofitable Branches, trom which there is no Expectation of good Fruit, whilst observing those that have well knit Melons

Vifit-

"on them at the ends of the Branches, I constantly take away the rest of that Branch on this side the Fruit, which divaricating into other useless Wanderers, would rob, and deprive the Fruit of the Nutriment derived from the Root; nevertheless with this Caution, that in Pruning, I spare some other less Noxious Branches to shade the Fruit that it be not lest quite naked, and expos'd to such a forching Heat as would hinder its Growth and Maturity, which within forty Days from its Nativity and knitting into Fruit, arrives to full Peasestion.

"Great and Pumpion like Melons are very feldom tolerably good, as arriving to their bulk either from the Nature of the Seed and Kind, or from fuperfluous Watering the smaller ones; wherevere (though as I faid they cannot support the too excessive Heats) the less Water you give your Plants (provided you find them not to want it) the better; and that rather a little at a time than much: Once a Week is for the most part sufficient. As to this therefore you must determine, and regulate your Refreshments with great Circumspection. and judge by the Nourishment which you conceive necessary to produce and maintain the Foot, with its Branches, and Leaves deriving from it; without, which no Kind and Genuine Fruit is to be ex-" pected.

"When you would gather a ripe Melon, you will have notice by its turning a little Yellow; for from that time within a day (as the Weather proves) it does ordinarily ripen, and begin to cast a grateful Scent; This Yellowness appearing in some Part of it or other, and not seldom with some Rists, or little Chass about the Stalk, &c. are most infallible indications of its being left rather too long, than too hastily gather'd: The Gard'ner must therefore not fail of

Q 2

"Visiting the Meloniere at the least three times a Day, Morning, Noon, and Evening, for this Critical time of ripening: He will sometimes find Melons ripen too fast, but they are seldom or never good, as proceeding rather from a sickly, or visiting Real than from the Nature of the Plant or

good, as proceeding rather from a fickly, or vicious Root, than from the Nature of the Plant, or Species of those I cultivate.

"After twenty four Hours keeping, or the next Day after it has been gather'd (for so long, contrary to Vulgar Opinion, it should be preserved in forne sweet dry place) and not eaten immediately as it comes from the Garden: A perfect and transferendent Melon will be full juicy, and without any Vacuity (which you'll easily discern by rapping a little with your Knuckles upon the outside of the Fruit) the Meat should also be dry, or but a little Rorid meazing out of the Pulp; but by no means Watrish and Flashy. To this add a Vermillion Colour, a grateful Flavor, and an high and Racy Taste.

"Lastly, Reserve for Seed of that only which lies

"Laftly, Referve for Seed of that only which lies, towards the Sunny fide of the Melon, which being immediately cleans'd from its Mucilage, with a dry Linnen Cloth, Referve in Boxes, or Papers,

" in some Temperate and sweeter place.

MINT, or Spare-Mint, is multiplied only by Runners, that are like fo many Arms that fpring out of its. Tuft, and take root, it is likewife propagated by cut-

tings; but bears no Seed.

Tis called in French, Balm; when once planted it, reeds no other particular Culture, then being cut down close to the Ground every Year at the end of Autumn, to make it shoot out Store of tender Sprouts in the Spring, which are mingled with the furnitures of Sallads, for them that love them; 'tis a little spicy and perfumed: It must be renewed every three Years at least, and placed always in good Earth; the Branches, when cut off take root at the place where they are covered.

cover'd, and by that means of one great Tuft we may easily make a great many, which are to be planted at the distance of a Foot one from the other; in the Winter likewise we plant some thick Tusts of it upon Hot-beds, and by taking care to cover them with Bells, they spring very well for about fisteen Days, and

then perish. MUSCATS, are a kind of Grapes, which when they attain to their natural goodness, are one of the most confiderable commodities of a Kitchen-Garden; there are three forts of them, viz. white, red, and black, the white is commonly the best of the three, it requires a temperate Country, and the expolitions of the South and East, and always a light Ground, we feldom see any good in pure Earth, and if it be in hot Climates, in gravelly and Sandy Grounds; they prosper very well upon Counter-Espalliers, or Pole-bedge-trees, and even in the open Air; their Goodness consists in having large, yellow, and crackling Berries, and growing thin in their Clusters, and in a rich musked Tast; but yet not too strong like Spanish ones. The Province of Tur.in produces admirable ones. Their Culture is exactly the same as the Chassela's Grapes, both as to their Pruning, and manner of propagation.

The Long-Muscat, called otherwise the Posse-Musquee, is another fort of Garpe, whose Berry is bigger and more longish than that of the ordinary Muscat, and its Clusters are also longer, but yet its Taste

is nothing near fo rich as that of the others.

N

NASTURCES, commonly called Capucin Capers, are multiplied only by Seed, which is a kind of Pea or Haricot, or French Bean, which climbs and gets up upon Branches or Poles which are near it; the Leaf of it is pretty large, and the Flower of an Orange Colour; the figure of the Seed is a little pyramidal, divided

vided by ribs, having all its superficies engraven and wrought all over, being of a gray colour, inclining to a light Cinamon: They are sown in Hot-Beds about the end of March, or the beginning of April, and afterwards are replanted by some Wall well exposed. The Seed easily falls as soon as ever 'tis ripe, as doth that of Borage, and Bells de nuit, or Night fair ones, and therefore they must be carefully gather'd.

0.

ONIONS, as well the white as the red, are multiplied only by Seed which as I have alredy faid, is

like that of Cibnuls.

They are either red or white, which last are sweeter and more prized than the red ones; there's no body but knowshow many uses they they serve for; they are propagated only by Seed, which is commonly fown about the latter end of February and beginning of March, in Beds of good Earth, and well prepared, and afterwards raked with an Iron Rake to cover them, as is done to other small Seeds: They must be fown thin, that they may have room to grow to their full bigness, and therefore if they come up too thick, they must be thin'd; by pulling some of them up as foon as they are big enough, which is towards the Month of May, which we transplant in order to use instead of Cibouls. Though the ordinary Season for fowing Onions be at the end of Winter, yet we may fow them in September, and transplant them afterwards in May, by which means we may have fome full grown at the very beginning of Fuly, which we may gather, plucking them first out of the ground as soon as that time comes; and then after we have dry'd them two or three days in the hot Sun, lay them up in some dry place, to keep all the Year in case of need. We must not forget when our Onions begin to appear with

pretty thick Stems above the Superficies of the Earth. that is, when they begin to advance towards their Maturity, to break them down either by treading them under our Feet, or with a Board press'd presty hard down upon them, because by that means, the nourishment that was before spent in their Stems, being hindred from mounting upwards, will all remain and fettle in that part, which (I think) is improperly called the Head, and make it grow fo much the bigger. I have already told you elfwhere, how their Seed is to be raifed.

PARSLEY, as well the common as the curled fort, is multiplied only by Seed, which is little and very small and of a greenish grey colour, and a little bending inward on one fide, and all over ffreak'd with little rifing Streaks from one end to the other. Both forts are of great use in Kitchensall the Year long, as well for its Leaves as Roots; it is comprehended under the title of Verdures, or green Pot-Herbs: We ought not to fail in the Spring, to fow a reasonable quantity of it in every Garden, and that pretty thick, and in good and well prepared Ground. When its Leaves are cut it shoots out new ones, like Sorrel; it refists well enough a moderate, but not a violent Cold, and therefore 'tis best to bestow some covering on it in Winter, to defend it. When we would have any of it to produce large Roots, we must thin it in Beds or Borders where it is fown; it requires pretty much wat'ring in very hot Weather. There are some who pretend to have a kind of Parsley bigger than ordinary, but for my part I know no fuch kind. The curled Parsley appears more agreeable to the fight than the common fort, but is nothing the better for that. We gather our Parfley Seeds in August and September.

PARSLEY

PARSLEY MACEDONIAN, or Allifanders, is also propagated only by Seed, which is pretty big and oval, and a little more full and swelling on one side than on the other, which hends a little inward, streak'd throughout its whole length, and is streak'd a-cross on the edges between the fides.

It is one of the Furnitures of our Winter Sallads, which must be whitened like our wild Endive or Succory, that is to fay, at the end of Autumn, we must cut down all its Leaves, and then cover the Bed where it grows, all over with long dry Dung, or straw Screnes fo close, that the Frost may not come at it, by which means the new Leaves that spring from it, grow white, yellowish, and tender. We sow it in the Spring, pretty thin, because it produces a great many large Leaves, and we gather its Seed the latter end of Summer; it is a good hardy Plant, and defends it self pretty well from the Drought, without requiring much watring.

PASS-PIERRE, Pierce-Pierre, that is, Pufs or Pierce-Stone, being a kind of Stone-Parsley, is multiplied only by Seed, which is more long than round, pretty big, of a greenish gray colour, striped on the back and belly, and refembling a Lute in Shape.

PARSNIPS are multiplied only by Seed, which is flat, and of a round figure, a little oval, and as if it were hem'd or edg'd, itreaked throughout its length,

and is of the Colour of a brownish Straw.

They are a fort of Roots well known in our Kitchens. We fow them towards the end of Winter, either in open Ground, or Borders, and that always pretty thin, and in good and well prepared Ground; and if they come up too thick, they must be thin'd as soon as May comes in, that they which are left may be the better nourish'd, and grow the fairer.

PEASE, are multiplied only by Seed; there are great ones, little ones, white ones, or yellow ones,

and green ones; all the World know they grow in Cods, and are almost round, and sometimes half flat.

They may be placed in the rank of Kitchen-Plants: It is a good ruftical or hardy Plant, which commonly is fown in the open Field, without needing any other Culture than being weeded whilst it's young that is, before it begins to cod; but when they are proprehey veild more than when they are not: They require pretty good Ground, and a little Rain to make them tender and delicate, and must be sown pretty thin. There are several forts of them, viz. Hastings, green, white and square ones, otherwise called large-codded Peafe, &c. We may have of them in the Months of May, June, July, August, September, and October; for to have some all that while, after the first, we have no more to do, but to fow them in different Months, to have them fit for eating three Months after. Those forts of which we are most choice in Kitchen-Gardens, are the Hastings both white and green, which are of a midling fize: We fow them at the end of Ottober, under the shelter of some Eastern or Soutbern Wall, and fometimes we also raise Ridges, or slop'd Banks for that purpole, and to dispose them to come up so much rhe sooner when they are sown, we make them sprout five or fix days before, by laying them to steep two days in water, and afterwards laying them in a place where the Cold cannot come at them 'till their first Root begins to appear. Hard Weather spoils them quite, which is the reason why all we can do will not procure us any good ones 'till the latter end of May: We likewise fow some upon Hot-Beds at the end of February, in order to transplant them by the fides of fome well exposed Wall, in case those fown at the latter end of October preceding happen to have been spoiled by the Frost. Our last time of fowing them is at Midsummer, to have them fit to eat about All-Hallowtide.

PIMPERNEL. See Burnet.

218 The Compleat Gard'ner. Vol. II.

POMPIONS, or Pumpions, or Pumkins. See Citrulls.

PURSLAIN, as well of the green, as red or yellow fort, is multiplied only by Seed, which is black, and extraordinary finall, and of a half flat roundish figure: To have a good Crop of this Seed, the Pursual Plants must be replanted at the end of May, at a full Foot distance one from the other; the Seed grows in little Husks or Shells, each of which contain a great many; and when we are to gather it, we cut off all the Heads from of the stalks, and lay them to dry a little in the Sun, and then we beat the Seed out, and fan or skreen it.

It is one of the prettyest Plants in a Kitchen Garden: which is principally used in Sallads, and sometimes in Pottages, there are two forts of it, the green and the red or golden; this latter is the more agreeable to the Eve and the more delicate and difficult to raife, so that in hard Weather we have much ado to make it grow even upon Hot-beds, and under Bells, for it seldom prospers in open Beds 'till about the middle of May, and then too the Earth must be very good, sweet and very loofe, and the Weather very fair; and therefore for our first Purstain which we are not to begin to fow upon Hot-beds till towards the middle of March, we must use only the green fort, because the yellow or golden fort dwindles away as foon as it comes up, unless the Season be a little advanced, and the Sun a little hor, which is towards the end of April: It is commonly fown very thick, because its Seed is so very fmall that it cannot be fown thin. When we fow it upon Hot-beds, either when it is cold, and that by consequence either Glass Frames or Bell-Glasses are needful, or in milder Weather, we only press down the Mould about it with our Hand, or with the Back of a Spade; but when we fow it in open Beds, which

must be well prepared for that purpose; we rake it

over five or fix times with an Iron Rake, to make the

Seed enter into the Ground.

The way to raise Seed from it, is to transplant some Plants of it that are big enough, into Beds well prepared, at the distance of eight or ten Inches; the Months of Fune and Fuly are proper for that effect, and then in a little time after, they are run up, and have done flow'ring; as foon as ever we perceive any of their Husks to open, and discover some black Seed, we must cut down all their Stems, and lay them some Days in the Sun, till all the Seed be quite ripened, and then we beat them out, and winnow them, &c. We must be careful to transplant each fort a-part by it felf, that we may not be mistaken in the Seed when we are to fow it. The thick Stalks of Purstain that is to run to Seed, are good to pickle in Salt and Vinegar for Winter Sallads.

R.

RADISHES, are multiplied by Sced, which is round, pretty thick, and of a redish Cinamon Colour; it grows in a kind of little Cods.

When Radishes are qualified with all the goodness they should have, that is, when they are tender, fnap eafily, and are fweet, are in my opinion one of the Plants that give the most pleasure of any in our Kitchen Gardens, and that give it as often and as long as any of them all, and I look upon them as a kind of Manna in our Gardens. There feems to be no great care required to make them grow, it being indeed only necellary to fow them pretty thin, in well prepared loofe and mellow Earth, and to water them foundly in dry Weather; and with this Culture they will attain all the perfection they are capable of. But the main Points hear in question, are first, to be atways provided with Seed of a good kind; and fecondly, take order to have Radishes without discontinuation

ation from February, 'till the coming in of the Frosts in the beginning of November: The Seed which is of a good kind, is that which produces few Leaves, and a long red Root, for there are some which produce a great many Leaves, and little Roots; and when once we are provided with Seed of a good kind, we must he extream careful to propagate it in some well prepured Spot of Ground, a Foot and a half afunder: Being so transplanted, they will run up, flower, and veild Seed ripe enough to gather by the end of July; and then we cut down all their Stems, and after they have been dry'd some days in the Sun, we beat out

Those Stocks of them that run to Seed, shoot up their Branches to fuch a heighth, and pulh out their Flowers so far, as if they knew not were to stop, and therefore it is good to pinch off those Branches to a reasonable length, that the first Pods may be the better

nourished.

the Seed, and winnow it, &c.

But it is not enough to raife good Seed, we must likewise take order to be supplied with good Radishes for eight or nine Months in the Year: The first that are eaten grow in Hot-beds, the manner or raifing which I have explain'd in the Works of November; and by the means of those Hot-beds we may have fome during the Months of February, March, and April, otherwise not; and in order to have some all the other Months, we must fow some among all manner of Seeds, they coming up so very quickly, that we have time to gather our Radishes before they can do any harm to the other Plants. Radishes are extreamly apprehensive of the excessive Heats in Summer, which makes them grow ftrong as they term it, too biting, stringy, and sometimes very hard; and therefore in that Season we should sow them in loose mellow Ground, where the Sun shines but little; and the best way will be to make up a Bed or two for that purpose along the fides of some Northern Wall, fill'd with

with Mould to the depth of a large Foot and a half, and to fow our Reddishes, there, and water them well. In Spring and Antonn, when the Sun is not fo hor, Radishes take well enough in open Ground, and in the open Air.

RASSBERRIES, both red and white, are propagated only by Slips that fprout out of their Stocks every Year in the Spring time, and are fit to replant the

next Spring after.

Both the white and the red begin to ripen about the beginning of fuly: They are planted in March, either in Beds or Borders, observing the distance of two Foot between Plant and Plant; they shoot out during the Summer many well rooted Suckers, some of which we take away to make new Plantations, by which means the old ones are likewise renewed, for they are dry as soon as their Fruit is gather'd. The only Culture used to them is, first, in the Month of March to shorten all their new Shoots which we perceive round about the Stock, and which ought only to be thickest and handsomest; and in the second place, to pluck away all the small ones, as likewise the old ones that are dead.

REPONCES, or wild Radishes, are propagated only by Seed, and are a fort of little Radishes that are eaten in Sallads, and grow without any Pains in the Fields.

ROCAMBOLES, are a fort of mild Garlick, otherwise called Spanish Garlick, which is multiplied both by Cloves and by Seed, which latter is about the bigness of ordinary Pease.

ROCAMBOLES. See Shallots.

ROCKET, being one of the Sallad Furnitures, is multiplied by Seed, which is extream little, and of a Cinamon, or dark Tan Colour.

'Tis fown in the Spring, its Leaf is pretty like that,

of Raddishes.

222 The Compleat Gard'ner. Vol. II.

ROSEMARY, is a little very odoriferous Shrub, that is propagated by Seed or Branches that have some share of Raot.

It is principally used for the persuming of Chambers; and in Decoctions for washing the Feet, it is multiplied in the same manner as Rue, and other Border Plants, and lasts sive or six Years in its place.

RUE, is multiplied by Seed, whose shape resembles that of a Cocks Stone; it is of a black Colour and rugged; but yet we usually propagate it rather by its

Layers and Cuttings, than by its Seed.

Tis a Plant of a very strong Smell, of which we plant some Borders in our Gardens, and is hardly of any use but against the vapours of the Mother.

S

SAGE, is multiplied only by a kind of hooked Slips

that have a little Root.

It is a Border Plant, whose Culture hath nothing of particular, but is like that of the other Border-berbs, as Rosemary, Lavender, Wormwood, &c. There is a fort that is party cloured, which to some People appears more agreeable than the common Sage, which

is of a palish green Colour.

SALSIFIE, or Goats-beard, the common fort is multiplied only by Seed, which is almost like in all things to Scorzonera, except in its Colour, which is a little grayer; it is of a very long oval Figure, as if it were so many little Cods all over streaked, and as it were engraven in the Spaces between the Streaks, which are pretty sharp pointed towards the ends.

SPANISHSALSIFT, or Scorzonera, is one of our chiefest Roots, which is multiplied by Seed as well as the others, and is admirable good boiled, both for the pleasure of the Taste, and the health of the Body. It is propagated only by Seed which is sown in March, we must be careful to sow it very thin, whether it

be in Beds or Borders, or else at least to thin it afterwards, that its Roots may grow the bigger. Scorzonera runs up to Seed in June and July, and is gather'd

as foon as it is ripe.

SASIFY Common, is another fort of Root cultivated after the same manner as the preceding one, but is not altogether so very excellent; they easily pass the Winter in the Ground, it is good to water both forts of them in dry Weather, and to keep them well weeded, and especially to put them into good Earth well prepared, of at least two full Foot deep.

SAMPHIRE, called in French Pierce Pierre, is one of our Sallad Furnitures, that is multiplied only by Seed, and which being by nature very delicate; requires to be planted by the fides of Walls exposed to the South or East, the open Air and great Cold being pernicious to it. We usually sow it in some Pot or Tub filled with Mould or else on some fide Bank towards the South or East, and that in March or April, and afterwards transplant it in those places above mentioned.

'Tis a kind of Stone Parfley, multiplied only by Seed which is more long than round, and pretty big, of a greenish gray Colour, striped on the Back and Belly, and refembling a Lute in shape.

SHALLOTS, or Eschalots, are multiplied by Offfets or Kernels which grow about the Foot of its Plant,

and are about the bigness of a Philberd Nut.

SHALLOTS, or Rocomboles, otherwise Spanish-Garlick, requires no other Culture than common Garlick, and are particularly remarkable, that there Seeds are as good to eat, as their Cloves taken out of the Earth. Their Seed is large, and ferves to propagate them as well as the Cloves or Kernels that compose their Root.

SMALLAGE, is multiplied only by Seed, which is reddish, and pretty big, of a roundish oval Figure, a little more full and rifing on one fide than the other, and is streaked from one end to the other.

SAVORY.

SAVORY, is an annual Plant, a little odoriferous, which grows only from Seed, and whose Leaves are used to some Ragous, and particularly among Pease, and Eeans; it is sown in the Spring either in Beds or Borders.

SORREL, as well the leffer fort, which is the common one, as the greater one, are both multiplied only by Seed, which is very fmall, flick, and of a triangular oval Figure, the ends of it being fharp and pointed, and being of an excellent dark Cinamon Colour.

ROUND-SORREL is propagated only by Shps, or Runners, fo that out of one Tuft we may eafily make feveral Plants of it.

WOOD SORREL, or French Sorrel. See Allelvia.

Sorrel, in Kitchen-Garden Terms, is placed under the Title of Verdures, or green Pot-Herbs, and accordingly is much nfed in the Pot. There are some forts of it that produce larger Leaves than others, which are called Sorrel of the greater fort; all the forts may be fown in March, April, May, June, July, and August, and in the beginning of September too, provided they be allowed time fufficient to grow big enough to refist the rigour of the Winter: We fow Sorrel either in open Ground, or else in straight-Rows, or Furrows, in Beds or Borders, in all which cases it must be sown very thick, because many of its Plants perish: It requires a Ground that is naturally good, or elfe well improved with Dung. Its Culture confilts in being kept clear from Weeds, in being well water'd, and being cover'd with a little Mould once a Year after it's first cut down to the ground. That Mould serves to give it new Vigour, and the Seasons most proper for applying it is in the hot Months of the Year.

It is most commonly multiplied by Seed, tho' sometimes we transplant some of it that thrives very well; we gather its Seed in Fuly and August, There is a particular fort of Sorrel, called round Sorrel, for the roundness of its Leaves, whereas those of the other fort are sharp and pointed; the tender Leaves of this fort are fometimes mixed with Sallad Furnitures. but it is ordinarily used in Bouillons, or thin Broths: it is multiplied by running Branches that take root in the Earth as they run over it, which being taken off and transplanted, produce thick Tufts, which also produce other Runners, and fo in infinitum.

SPINAGE is multiplied only by Seed, which is pretty big and horned, or triangular on two fides, having its Corners very sharp pointed and prickly, and the other part which is opposite to those two pointed

Horns is like a Purse, of a greyish colour.

It requires the best Ground, or at least that which is most amended, or improved. They are multiplied only by Seed, we fow them either in open Ground, or else in Furrows in straight Rows upon well prepared Beds, and this we do feveral times in the Year, beginning about the fixteenth of August, and finishing a Month after; the first are fit to cut about the middle of Ollober, the second in Lent, and the last in Rogation time; those which remain after Winter run up to Seed towards the end of May, which we gather about the middle of *June*: When they are once cut, they spring up no more as Sorrel does. All their Culture confifts in keeping them clear from Weeds, and if the Autumn prove very dry, it is not amiss to water them sometimes. They are never transplanted, no more than Chervil, Cresses, &c.

SKERRETS, are a fort of Roots propagated by Seed, and cultivated like other Roots, as is directed

in the Month of March.

STRAW BERRY Plants, as well the white as the red, and those called Caprons, are propagated only by Runners, which are produced by a kind of Thread or Strings, which springing out of the Body of the Plant, in a most no annie & it was R. itak

and creeping along upon the Earth, eafily enough take Root at certain Joints or Knots about a foot diffance one from the other; which Knots coming to take Root, make new Plants, which in two or three Months time are fit to be transplanted; they are plac'd three or four of them together to make what we

call a Tuft.

STRAWBERRIES: It is observed that a Plantation of them taken out of the Woods, turns to better account when transplanted, than one flipt off from the Garden Strawberries. We plant them either in Beds or Ecrders, both which must be well prepared, amended, and labour'd, and ffirr'd up in one manner or other: If it be dry or fandy Ground, both the Beds and Borders must be funk a little lower than the Alleys or Path-ways, the better to retain the Rain that falls, and the Water we bestow on them; a contrary course must be taken, if we plant them in strong, heavy, and fat Farth, that is almost pure Clay, because excesfive Moisture rots the Roots: We place them usual-Iv nine or ten inches afunder, putting two or three Plants in one hole, which is made with a Planting-Stick; the left time to plant them, is during the whole Month of May, and the beginning of June, that is to fay, before the great Heat comes in; we may also plant them all the Summer Season in rainy weather. It is particularly requifite to plant Nurscries of them in May, and that in some place near the North quarter, the better to shelter them from the violent Heat of the Summer Sun; and then we plant them about three or four inches afunder: but when they are grown big enough there, we transplant them afterwards in September, in order to make Beds or Squares of them, according as we find occasion to have a greater or less quantity of them. Their Culture consists chiefly, First, in watering them well in dry Seafons; Secondly, in leaving but a moderate number of Stems or upright Shoots, to every Stock three or four of the most

most vigorous Shoots being enough; in the third place, in leaving but three or four Strawberries of them that appeared first and nearest the Stock on every Stem. and therefore we must pinch off all their other numerous Blossoms that grow out at the end of those that have already bloffom'd, or are still in bloffom, becarfe none but the first produce any fair Strawberries, scarce any of the last being ever known to knit, or come to any Perfection, but when we are careful to pinch them off judiciously, we may be affured always to have good Strawberries. I have already given Directions in the Works of the Month of February, how to raise hasting Strawberries. Curious Persons have usually two Strawberries of two feveral Colours, viz. red and white, but they place them in feveral Beds. The great Enemy to Straw-berry-Plantations, are the Tons, which are great white Worms, that in the Month of May and Fune gnaw the Neck of their Roots, and so kill them: To prevent which, in those Months we should carefully fearch every Day, under the Roots of all the Strawberries that begin to wither, where we shall commonly find one of these great Worms, which after they have done a mischief to one, pass on to do the like to cther Strawberry-Plants, and kill them in like manner.

Strawberry-Plants bear very well the Year after their planting, if planted in May, but yield very indifferently if not planted till September after they are taken out of the Woods; yet in the fecond Year they bear wonderfully; but that being past, they produce very pitifully, and therefore 'tis good to renew them every two Years: It is likewise very convenient to cut off every Year their old Tops, when the Strawberries are gone, which is commonly at the latter end of July. The earliest Strawberries that ripen towards the end of May, are those that are planted by the fides of Southern or Eastern Walls, and they

R 2

228 The Compleat Gard'ner. Vol. II.

that ripen last, are such as are planted in a Northern Exposition.

SUCCORY. See Endive.

T

TIME is multiplied by Seed which is very finall, fometimes we feparate those Plants or Stems of it that produce several rooted Slips or Suckers, to replant them in Borders; for Time is seldom planted otherwise.

'Tis an odoriferous Plant, which is multiplied as well by Seed as rooted Branches or Slips. A Border of *Time* is a confiderable and necessary Ornament

in our Kitchen-Garden.

TRIPE-MADAM, is propagated both by Seed, and Cuttings or Slips, every Stem or Stock of it produceth feveral Arms, which being feparated and replanted, easily take Root again; the Seed of it is grey, and longish, and almost of the shape of Parsley feed; there grows a great deal of it upon every Seed-stalk, which runs up above one another like those of Seed Carrots, &c. there are seven or eight of them in a fort of little open Cup, where they grow ripe, after the falling of a little yellow Flower inclining to an Olive Colour.

It is one of our Sallad Furnitures, used chiefly in the Spring when 'tis tender, a little of it ought to ferve in the Summer, because it is then too tough;

'tis multiplied both by Seed and Cuttings.

TURNEPS are multipled only by Seed which is

almost like that of Cabbage.

They are not properly Kitchen-Garden Plants, but yet where they are spacious, they may be admitted into them. They are sown very thick in Beds, some in March, and others in August; we gather their Seed in July and August: Every Body so well knows

the

Vol. II. The Compleat Gard'ner. 229

the use of them, that I need not say any more on

this point.

TARRAGON is one of the perfuming or spicy Furnitures of our Sallads, it is propagated both by rooted Slips, and Seed; it fprings again feveral times after it is cut; it endures the Winter, and needs but little watering in the drieft Weather in Summer; when we plant it, we must allow eight or nine inches distance between Plant and Plant in the Beds; the best time to plant in, is in March and April, which hinders not but that we may transplant it again in the Summer Seafon.

VINES, of all forts, whether white, red, &c. are multiplied by Layers, by hooked or bent Slips, and especially couched, and lastly by grafting cleft-wise. VIOLET Plants, as well the double as single fort,

and of what colour foever they be, though they produce Seed in little reddish Shells or Husks, yet are multiplied only by the Slips they produce, each Plant or Stock of them growing infenfibly into a great Tuft, which is divided into feveral little ones, which being replanted, grow in time big enough to be likewife divided into others.

VIOLETS, especially the double ones, serve to make pretty Borders in our Kitchen Gardens; their Flowers make a very agreeable Figure when they are artfully placed on the Superficies of Spring Sallads. Every Body knows that they are propagated by Tufts, that is, by dividing one great Tuft into feverallittle ones, which likewise in time grow thick, and fit to be di-

vided into other little ones.

Vol II.

W.

WORMWOOD is multiplied by Seed, which is of a pretty odd figure, being a little bent inward in its smallest part, and a little open on the other end, which is bigger and rounder, and upon which there is a little black spot; its Colour is yellowish at the bigger end, and its fharper end inclines to black; its Seed is feldom used, because it is very difficult to fan, being very light; and therefore when we have need of propagating Wormwood, we make use rather of its Cuttings that are a little rooted.

The Plants of this and all other Plants placed in Borders or Edgings, which are therefore called Border-Plants, as of Time, Lavender, &c. are planted by a Line, and at the distance of two or three inches, and five or fix inches deep in the Ground. It is good to clip them every Spring, and to renew them every two Years, and to take away their oldest and decayed Stocks; their Seed is gathered about the

Month of August.

THE

Gardner's Kalendar,

Directing what is to be done in a

KITCHEN-GARDEN

Every Month in the Year:

With what

PRODUCTS

We may have from our Gardens in every Month in the Year.

AND

How to know if any thing be wanting, which it should be stock'd with in every Month.

Works to be done in a Kitchen Garden, in the Month of January.

RUNE all forts of Trees, whether Dwarf or Wall-Trees, to prepare some of them to plant as foon as ever the Ground shall be open after the hard Frosts, and the melting of the Snow that cover'd it.

MakeTrenches to plantTrees, dig Moulds to amend them; dig round the feet either of Trees over-luxuriant, to cut off their thick Roots, and by that means to make them fructifie, or of fuch as are infirm, to trim and redrefs them.

Make Het-beds to fow forward Coucumbers, and Sallads in, whether in Rows or little Furrows, or under Bells, to make Skicens to cover those Seeds in case of need.

The first Hot-beds for Coucumbers, as also for Muskmellons, are usually made at the very beginning of the Month, and at the same time we may make Hot-

beds for Mushrooms.

Heat or force Asparagus.

Heat Beds of Sorrel, Patience, Borage, &c. Raife on Hot-beds, Facinihs, Narciffus's of Con-

flantinople, and some Tulips, &c.

Pull down the Hot-beds of the last Year, to take the rotten Dung that composed them, and lay it upon those Grounds we would amend or meliorate.

Lay apart fome Moulds to have them at hand to prepare for the Hot-beds, also clear and cleanse the places of the Het-beds, in order to the making of new ones.

Tie up with Bands of Straw; the tops of the Leaves of long Lettuce which have not cabbaged, to make them cabbage, or at least to whiten them when they are grown big enough for it.

Raife some Strawberries upon Hot-beds, to have

them ripe in April and May.

Dung Fig Trees in order to have early Figs.

And in fine, advance the doing by little and little, all that the Spring Season is wont to do, with an ex-

traordinary expedition.

Plant Trees in Baskets, pot and case Fig Trees; lay Vine and Fig Tree Eranches, clear your Trees of Moss, if troubled with it, which is done best in Rainy Weather, with the back of a Knife or some such Instrument.

But

But it would be to little purpose to know what to do, without being informed how to do it, and therefore for your Instruction in Pruning, I refer you to the Fourth Book, in which, my having treated throughly on that Subject, may excuse me from

speaking any more of it now.

As to the way of making Hot beds, first you must know they are to be made only with long Horsedung, or Mule-dung, which is to be either all new, or mixed with a third part at most of old, provided it be dry, and not rotten, for that which is rotten is not at all proper to make Hot-beds, no more than the Dung of Oxen, Cows, Hogs, &c. as well because it has little or no heat, as because ordinarily these kinds of rotten Dunk are accompanied with an unpleafing fmell, that infects the Plants raifed upon fuch Beds, and gives them a scurvy taste.

By new long Dung is to be understood, that which is taken from under the Horses, and has served them

for Litter one Night, or two at most.

By long old Dung, is meant that which has been piled up ever fince it was new, in a dry place, where it has lain all Summer, to be ready to be used, either to make coverings for Fig Trees, Artichoaks, Endive, &c. against the Winter Cold, or to make Hot-beds after the ordinary manner, which is thus

performed.

After we have marked out, and proportioned the place where the Bed is to be and marked out likewife with a Cord or with Stakes of what breadth it must be, there must be brought a rank of Baskets full of long Dung, one at the tail of another, beginning the rank or row where the Bed is to end; which done, the Gard'ner begins to work where the rank of Baskets ends, that fo the Dung, not being intangled with any thing lying upon it, may more eafily and handfomly be wrought into the Bed. Then the Gard'ner takes up this Dung with a Fork, and if he be any thing han234 The Compleat Gard'ner. Vol. II.

dy places it so neatly and tightly in laying every layer of his Bed, that all the Straw-ends of the Dung are turned inwards; and what remains ferves to make a kind of Back, or Fence on the outfide. The first Layer being thus compleated exactly to the breadth that is marked out, which is commonly of about four foot; and to fuch a length as is thought fit, the Gard'ner proceeds to lay the tecond, third, &c. beating them with the back of his Fork, or elfe treading them with his Feet, to fee if there be any defect; because the Bed must be equally stuff'd every where, fo that no one part may not be less strong of Dung than another; which being done, he continues it to the defign'd length, proportionating it still by Layers, till the Bed reach the length, breadth and heighth it should have; which heighth is of between two or three foot when it is first made, for it will fink a full foot when it is fettled.

In the fecond place, there are other Hot-Beds which are to serve for Mulhrooms in all the Seasons of the Year, and fuch may be made every Month, tho' they act not till about three Months after they are made; and that is when all their great beat being quite spent, they are grown mouldy within: This fort of Beds are made in a new, fandy Ground, in which is first made a Trench of about fix inches deep; then we cover them with a Layer of about two or three inches thick of the same Earth; they are raised in form of an Ass's Back, and over the covering of Earth we lay another of five or fix inches of long dry Dung, which ferves in Winter to shelter the Mushrooms from the Frost, which destroys them; and in the Summer, from the great Heats that broil them; and likewise to prevent the same mischievous effects of the same excessive Heat, we further take care to water these Mushroom.

beds twice or thrice a Week.

As for the breadth of Hot-Beds, it should be in all forts

forts of them of about four foot, and their heighth must be of between two and three when they are first made, because they fink afterward a full foot, when once the great Heat is past: As to the length, that is to be regulated by the quantity of Dung we have to make them with; fo that according to that, we make of them feveral lengths: But in heighth and breadth, all Beds should be as near as may be alike

proportioned.

But before we fow or replant any thing whatfoever upon any new made Hot-beds, the first Precaution we must observe, is, To stay six or seven Days, and fometimes ten or twelve, to give the Bed time first to heat; and afterwards, to give time for that heat which is very violent, to abate confiderably: this abatement appears when the whole Bed is funk, and when thrusting down our Hand into the Mould, we perceive in it but a moderate heat: Then it is we are to begin handfomly to shape out and adjust the Mould; for which purpose, the Gard'ner must make use of a Board of a foot broad, which he places upon the fides of the Bed, about two inches from the edge; and joining close to the Mould; and having thus placed it he endeavours to keep it firm and tight, as well with his Left-Hand and Knee, as with the strength of his whole Body; and then with his Right-Hand he begins at one end to press down the Mould against the Board, so hard, till he brings it to so firm a confiftence, that how light and loose soever it were before of its own Nature, yet it may be able to keep up it felf alone when the Board is taken away, as well as if it were a folid Body. When the Mould is thus adjusted to the whole length of the Board, then he removes the Board to another place. and fo continues till he has performed the fame operation on all sides of the Bed: And if the Board be a little longer, and confequently a little more unweildy than ordinary, then there must be two or three

persons join together to work in the same manner, and at the same time, to adjust this Mould; or if the Gard'ner be all alone, he must keep the Board tight with some Pins fastened in the sides of the Dung-Bed already adjusted; and when the thing is done, the Mould shall have at least a full half foot extent less on every fide, than the lower part of the Bed; and in its oblong square Figure, appear as even as if it were a Bed formed on the plain Ground: After which the Beds are to be employed for those occasions that first obliged us to make them. All things in them would either perish, or be much endamaged, if we fowed or planted in them fooner, or if we should delay our doing it any longer. The Heat of the Bed, may last in a condition to be able to perform well its effects for about ten or twelve Days, after it is fown or planted, but when that time is past, if we perceive the Bed to be too much cooled, we must renew the heat with some new long Dung, or fresh warm Litter apply'd round about it, both to recruit the heat, and to maintain it afterwards in that good temper in which it should be, and in which it was before, when we begun to fow and plant there; fo that the Plants instead of wasting away or perishing there, they may increase and thrive visibly, as they should do. It is not so very needful to tell you that when a Man has two Beds next one another, one recruiting of heat will ferve for both, because there's no body but knows it; but it is good to know that this recruiting of heat between two Beds, should not be by a great deal fo strong as when there is but one; for the ordinary interval or space left be-between two Beds for the path being about the breadth of one full foot, a little Dung will ferve to fill it up; and that new heat is reciprocally maintained in it's vigour by the neighbourhood of the two Beds that border on each fide upon it; but when there is but one Bed, our addition of Dung

Dung for a new Heat, must be at least two foot broad all along the whole length of the Bed, and to its full heighth, and many times it must be higher

than that.

When we are to renew the Heat, it is not always necessary to make an application of new Dung, it being many times sufficient to stir that at the bottom upwards, which we last applied, and which needs it, provided it be not too much rotted; which stirring of it is enough to renew the Heat for eight or ten Days longer: And there is no need of applying any new Dung, but when by the rotting of all the last, or of at least a good part of it, we find it to be no longer fit to yield that heat which is necessary to those Plants that are raised in Hot-beds.

If they are Asparagus, or Strawberries, which we have taken out of their cold Beds, and replanted in hot ones, and there be any apprehension of Cold, we must carefully cover them with Glass Bells, or Glass Frames, and to hinder the Frost from penetrating even them, and spoiling what is underneath them, we use besides to cover them with Skreens of dry long Dung, or Litter, or Straw which we put over the Glass Bells, or Glass Frames; and Plants never fail to produce upon Beds thus accommodated and maintained in a due heat, by such recruitings renewed from time to time.

This manner of proceeding is good and commodious enough for *Sorrel*, because being animated by the moderate heat of the *Hot-bed*, it springs up there for some fifteen Days time, just as it does when it grows in naked Ground in the Month of *May*, and afterwards dies; but it is not so good for *Asparagus*, because they, when they are pull'd up and replanted, never produce such sine *Shoots*, as when they are dunged and heat on the naked Ground.

It follows then, that the best method for Asparagus, and even for Serrel too, is to take up for about

two foot deep all the Earth in the Paths between two cold Beds, (which Paths should be a full foot broad) and fill them up afterwards with long warm Dung, to heat the neighb'ring Earth? and if it be for Asparagus, to cover the whole cold Bed with the same Dung, to help to warm the Earth; and when the Asparagus begin to sprout, we put Bells upon each Plant, or else cover the whole Bed with Glass Frames: after which. the Heat of those Paths must be renewed, by stirring them the bottom upward, or by renewing from time to time an application of fresh Dung covering besides the Bells or Glass Frames with dry long Dung, or Skreens of Straw, or fuch like matter, for the reasons above expressed, when we were treating of Asparagus and Sorrel in Hot-beds. The Asparagus-Plants being thus warmed, and feeling under those Bells or Glass Frames an Air as comfortable as in April or May, they produce Shoots that are red at first coming up, but which afterward turn green and long like those which Nature it felf produces in warm and temperate Seafons. The only inconvenience of those Artificial Heatings, is, that because they must be very violent to penetrace a cold Earth, they dry up and spoil those Plants; to that fuch Asparagus, instead of continuing fifteen Years together to bear well, as otherwise they do, never fpring kindly afterward; and though they be let alone two or three Years after their first heating, yet at most are able to endure but one more.

The Strawberries which are forced on Hot-beds begin to put out their Shoots in Fanuary, and flower in February and March, and yield their Fruit in April and May; the best method of raising them, is to put them in September in a tolerable good light Earth, and afterwards to plant them in Hot-beds in December; they may also be planted in Hot-beds without potting atall in the Month of March; their Runners, and some of their Leaves, must be taken off, if they have too many; the Earth in their Pots must be always kept loofe

and a little moist; and if there happens any excessive *Heats* in some days of *March* or *April*, they must have a little Air given them towards the North, and

they must be covered a Nights.

To have little Sallads of Lettuce to cut, mixed with Chervil Cresses, &c. with Furnitures of Mint. Tarragon, &c. and to have Radishes, &c. we make fuch Hot-beds as I have directed, and we steep in Water, about 24 hours, a little Bag of Lettuce Seed; after which time we take it out, and hang it in a Chimney-corner, or in some other place where the Frost cannot reach it; and the Seed so wetted drains it felf from the Water, and heats in fuch a meafure, that it sprouts; and then after we have made in Hotbeds some little Furrows of about two inches deep, and about as much broad, with a little Stick that we draw hard over Mould, we fow that sprouted Seed in those Furrows so thick that it covers all the bottom of the Furrows: There must be a French Bushel, or twenty Pound weight English, to fow a Bed of fourteen fathoms long, and of four broad; and when it is fown, we cover it with a little Mould, caft upon it lightly with the Hand, and each caft of the Hand dexteroully performed, should cover a Furrow as much as it needs; which done, we put fome Bells or long Straw over them, to hinder the Birds from eating them, and the Heat from evaporating, or the Frost by chilling it, from destroying the Seed; we take away the Straw, when at the end of five or fix Days the Seeds begin to spring well, and at length, ten or twelve Days atter, it is commonly high enough to be cut with a Knife, and eaten in Sallads, that is to be understood, if the Ice and Snow, and even the Heat of the Bed be not too excessive. We take the fame course with Chervil, and Cresses, save only that they must be fown without steeping their

As for Mint, Tarragon, Cives, and other Furnitures of Sallads, they are planted on the Hot-beds in the fame manner as the cold ones.

As for Radifbes, we feldom freep them to make them sprout, the Skins of their Seed being so tender, that in less than a Days time they would be all melted to a Pap.

I have directed how to fow Radishes in the Works of November, where we treat of preparing the Provisions we would have from our Gardens in Fanuary,

February, and March.

It is convenient to fow in the beginning of this Month, or even in November and December, a Hotbed of Parsley, to supply us with fresh in the Spring time, to ferve us till that we should fow in naked Earth at the end of February, be grown to its Perfection.

To lay the Branches, or Slips of Vines, Goofeberry, and Curran Bushes to take root, we need only couch, or lay down their Branches into the Earth, and cover them in the middle with Earth, to the heighth of five or fix inches, which are to remain in that condition till the Month of November following, when having taken Root, we take them up, that is, separate them from the Tree, and plant them where we have occasion for them.

To circumpose Trees, by planting them in Baskets. Pots, and Boxes or Cases, we first fill half way with Earth, those Baskets, Pots, or Boxes, and then having pruned and trim'd the Trees as I have directed in the Treatife of Plantations, we plant them, finking the Baskets or Pots quite into the Earth, but leaving the

Boxes or Cafes above Ground.

The way of potting the bulbous Root Tuberenses, Fanquils, Narciffius's of Constantinople, &c. is first to put them into Pots, and then to put those Pots into Hot-beds, covering those Beds carefully with Glass

Frames, Bells, Straw Skreens, &c.

To warm or force Fig-Trees, we must have some in Boxes or Cases, for which we make in January, a deaf Hot-bed, (being a Hot-bed made in a hallow dung into the Earth, and raised only even with its surface) and place the Boxes upon it. Then must we have some square Glass Frames about six or seven Foot high, which must be apply'd against a Wall expos'd to a Southern Aspect; by which the Dung in the Hot-bed frementing into a Hear warms the Earth in the Box, and by consequence makes the Fig Tree sprout: That Bed is to be put into a new Ferment when there is occasion, and great care must be taken to cover those Glass Frames close, that no Cold may get within them.

During the whole Month of January, we continue to fow upon Hot-beds under Bells, Lettuces to be replanted as I have directed in the Works of December; as also to replant them under Bells, as well to ferve in the Nursery as in the places they were design d for; and as to the Seeds when sown, we may storbear covering them with Mould if we please, it being enough to pat them with the flat of our Hands upon the Beds, to press the Mould close about them; we use the same method with Purskin sown under Bells, for we can scarce throw too little Mould upon those Seeds to cover them.

To have some sine little Lettuces for fallading, we must sow under Bells some of the bright curled fort, and stay 'till it has shot forth two Leaves before we gather it: The Seeds of those Lettuces must be sown thin, that the Plants may grow tall; and if we see them come up too thick, we must thin them: The choicest fort of Lettuce for the Spring Season, are the curled, fair or bright Lettuce, the short Lettuce, and above all the Shell-Lettuce, &c. We also sow some under Bells, to replant again, Borage, Bugloss, and Arrach or Orage.

Products that we may have from our Gardens in the Month of January.

B Esides' the good Pears following, viz. Leschasseries, Ambrets Thorn Pears, St. Germains dry Martins, Virgoulees, and Winter Bon Cretiens, &c. and these good Apples, viz. Calvils, Pippins, Apis's, Curpendu's, or Short Stalk'd Apples, Fennellets, or Fennel-Apples, &c. And laftly besides some forts of Grapes, as the ordinary Muscat, the long Muscat, the Chasselas, &c. every Person may have Artichoaks, &c.

All forts of Roots, as Beet-raves, or Red-Beet-Roots, Scorzoneras, Carrots, Parsnips, Common Salsifies, or

Goats-beard, Turneps, &c. Spanish, Cardons, and Chards of Artichoaks whitened.

Cellery whitened.

Macedonian Parsley, or Allisanders whitened.

Fennel, Anis, and Endive, as well that which is called the white, as that which is called wild, or

Suggery.

Collyflowers, &c. All these things must have been brought into the Confervatory in the Months of November, and December, and ordered as I have directed in speaking of the Works to be done in those two Months.

Befides which we have also Pancaliers, Milan, and

bright or large fided Cabbages.

These forts of Cabbages are not carried into the Conservatory; on the contrary, they must be Frost bitten in the open Air, to make them tender and de-

We may also have some Citruls, or Pumpions, and fome Potirons, or flat Pompions by the help of a Confer-

vatory.

We may also have pickled Cucumbers, pickled Purflain, pickled: Mushrooms, and pickled Capucin Capers, or Nasturces.

We

Vol. II. The Compleat Gard'ner. 243

We may have Onions, Garlick, and Shallets, out of the Confervatory.

With Leeks, Ciboulas, Burnet, Chervil, Parlley,

and Alleluja or Wood-Sorrel, &c.

Also very good reddith green Asparagus, which are better than those that grow naturally in April, and

all the Month of May.

And by the help of Hot Beds, or heated Path-ways, we may have very fine Sorrel, as well of the round as the long fort, and little Sallads of Lettuce to cut, with their Furniture of Mint, Tarragon, Garden-Cresses, tender Chervil, Parsley, Borage, Bugloss, &c.

We may likewise have little Raddishes upon Hotbeds, provided the abundance of Snow, and the rigour of the Frosts be not so several great, that we cannot so much as for a few Hours in a Day uncover the Beds on which they are, nor give them any new recruits of Heat, without which all that is planted of this fort on Hot-beds, is subject to grow yellow and come to nothing.

Likewise we may have Mushrooms upon Hot-bed made on purpose for that effect, and which are kept carefully cover'd with long dry Dung, to prevent the

hard Frosts from spoiling them.

Nor have we naturally but few Flowers, except Lawrel-time, and Snow-drops, but by the help of Hotbeds we may have some single Anemonies, Winter Narchisses's, and Narchisses's of Constantinople, Crocufes, &c. but we have now Laurus Rose-Leaves to garnish the Dishes we serve up to Table.

How to judge certainly by viewing and visiting a Kitchen-Garden, whether there be any thing wanting in it, which it should be stock'd with in the Month of January.

T is no inconfiderable thing to understand certainly, not only what Provisions a Kitchen-Garden well maintained and orderd may furnish us with every Month in the Year, but likewise what Works are to be done there every Seafon by an able Gard'ner; but yet that is not enough to make a Gentleman fo knowing as to be able to give himself the pleasure to judge certainly by viewing his Kitchen-Garden, whether it be fo well flock'd as to want nothing that it should have. For in fine, we must not expect always actually to find in it all Advantages for which we are beholden to Gardens. We know indeed that it should bring forth a provision for the whole Year, but we know very well too that it does not bring forth all Days in the Year; for Example, In the Winter Months we hardly see in it any of its Productions, the most part of them being carried out, and laid up in Store-houses, and Confervatories. And besides, among the Plants that are to be feen in it at other times, how many of them are there which have not attained to their Perfection, which yet ought to make a Figure in this Garden, tho' they require perhaps two or three, or perhaps five or fix Months time to arrive at it? Thus it is in the beginning of the Spring, with all Legumes, or eatable Plants and green things; and thus it is too in the Summer, with the principal Fruits of other Seafons; upon which confiderations, I thought it not impertinent, nor unuseful, to shew yet a litle more particularly, wherein the excellency and accomplishment of a Kitchen Garden does confift, judging of it according to the proportion or what we ought to find every time

we go into it.

I will begin with the Month of January, in which we ought to be very well fatisfied with the Garden in question, if we find in it a reasonable quantity of Winter Lettuces planted in Borders by Walls, and cover'd with long Straw, or Straw Skreens; and likewife if we find in it fome fquares of Artichoaks, and Bert-Chards well cover'd with long Dung, with the like Provision of Cellery, Endive, common Parsley, and Macedonian Parfley, or Alifanders, &c. and order'd after the fame manner: And in the third place, some Winter Cabbages, Cibouls, Sorrel, and Sallad Furnitures, and if thefe too last be shelter'd with some fort of covering; and in the fourth place, if there be fome fquares of Asparagus without any other Artifice than what is used to warm and force them in their cold beds, as I do and have begun to do in the Months of November and December, all other Kitchen-plants must be housed and laid up, as Roots, Onions, Cardons, Artichouks, Collyflowers, &c. In the fifth place, we may be content if we find the Fig-Trees well cover'd, all places where Trees should be well fill'd up with Trees, or at least with hole; dig'd, and Trenches prepared ready for planting them, or the Roots of those that begin to languish bared and laid open, in order to their cure: Sixthly, if we fee Men buffe in clearing the Fruit-Trees from Moss, and other Filth that spoils them; and if over and above that, we find there any Hot beds for the Novelties of the Spring time, fuch as are Strawberries, Raddishes, little Sallads, Peas, Beans, Cabbage Lettuces, Parsley, Cucumbers, and Musk-mellon Plantations &c. if we likewise find some Fig Trees and some other Trees forced, and advanced by artificial warmth; what then ought we not to fay in praise of the Gard'ner, especially if we find the Walks and Alleys kept neat and clean, and no Garden Tools and Utenfils any where neglected.

246 The Compleat Gard'ner. Vol. II.

Having told you what should compose the Beauty of a Kitchen-Garden in the Month of January, I think it needless to add any description of what makes it imperfect and disagreeable, as well in that Month, as in all the rest of which I shall afterwards treat, because any body may easily discern of himself, that it is just the reverse of what I have now spacified that is to say, a want of any thing that should be in it, Negligence and Slovenliness being look'd upon as the Monsters of a Kitchen-Garlen.

Works to be done in February.

N this Month we continue the same works we

were doing in the last, viz.

Now we apply our selves to manuring the Ground if the Frest permits, and about the end of the Month, or rather towards Mid-March, or latter, that is towards Mid-April, we sow in the naked Ground those things that are long a rearing as for Example, all forts of Roots, viz. Carrots Parsnips, Chervils or Skirrets, Beet-Raves, or Red-Beet-Roots, Scorzoneres, and above all Parsley Roots.

For now also Onions, Leeks, Cibouls, Sorrel Hafting Peas, Garden or Marsh-Beans, Wild Endive, or

Succory, and Burnet.

If we have any Shell-Lettuces that were fown in Autumn last, in some well shelter'd place we now replant them on Hot Beds under Bells, to make them Cubbage betimes. And particularly we take care to replant on them some of the Curl'd Bright Lettuces, which we sowed last Month, because they turn to better account than others.

Begin at the latter end of the Month to fow a little green Purslain under Bells, the Red, or Gol-

Vol. II. The Compleat Gard'ner. 247

den fort being too delicate or tender to be fown before March.

Replant Cucumbers and Musk-mellons, if you have any big enough, and that upon a Hot-Bed, in fome place well shelter'd either by Walls, Straw, or Reed Hedges, or some other Invention to keep off the Wind.

We also fow towards the end of the Month, our *Annual Flowers*, in order to replant them again at the latter end of *April*, and the beginning of *May*.

Sow also your first Cabbages.

Begin to graft all forts of *Trees* in the *Cleft*, prune and plant them; plant also *Vines*, and about *Mid-Vebruary*, if the Weather be any thing fair, is the proper time to begin all forts of Works.

Now make the *Hot-Beds* which you have occasion to make use of for *Radishes*, little *Sallets*, and to raise those things which we are to replant again in the *Cold*

Beds.

Take care to maintain the necessary heat about your

Asparagus, and to gather those that are good.

Continue to plant Trees when the Weather and the Soil will permit.

Provisions and Products of February.

THE Weather usually begins to grow a little milder this Month, so that as to Flowers, we may now naturally by the favour of a good Shelter and a good Exposition, have of all those forts which I told you in my Discourse of the Products of the last Month might be raised by forcing on Hot Beds. Besides which, we may have some Primroses, and the heat of the Hot Beds may even produce us some Tulips, and Totus Albus's.

But in respect of Kitchen-Plants, we have as yet only those things which we have before mentioned;

4 that

that is to fay, we continue to fpend the Stock we have in the Conservatory or Store house; and what we raife by the affistance of Hot-beds, and artificial heatings, as little Sallets, Sorrel Raddishes, Asparagus, &c.

How to judge certainly by viewing and visiting a Kitchen Garden, whether there be any thing wanting in it, which it should be stock d with in the Month of February.

F towards the latter end of this Month, the Weather appear pretty temperate, and there happen fo confiderable a Thaw as to promife an end of the great Cold, our Gard'ners should then begin to dig and manure the Squares and the Counter Borders, prepare the Cold beds, fow those forts of Seeds that are long coming up, as Parfly, Onions, Cibouls, Leeks, &c. They must likewise now earnestly mind the pruning of Trees, as well Dwarfs, as Wall-Trees, and pallifade or nail up these last for the first time, and particularly they must take care to make Hot-beds for the replanting of Musk-melons and Cucumbers, and for little Sallets, Raddishes, Cabbage-Lettuces, &c.

Works to be done in March.

A T the beginning of this Month, it appears who are the Gardiners that have are the Gard'ners that have been idle, by their not furnishing us with any thing with the diligent and skilful ones fupply us with, and by their having neglected to fow their Grounds, which lie for the most part as yet unfown, tho' the Weather have been favourable for it.

Good Gard'ners ought to cover with Mold, the Cold Beds which they have fown with their defigned Seeds,

Seeds, for fear the waterings and great Rains should beat down the Earth too much, and renders it Superficies too hard for the Seeds to pierce and shoot through; they should also bank up their Cold beds tightly with a Rake, that so the Rain-water, or that of their waterings may keep in them, and not run out of them into the Paths.

About Mid-March at furthest, make the Hot beds in which you are to replant the earliest Musk-

melons.

Sow in the naked Earth, in some well shelter'd place, all those things which you are to plant again in the like; as for Example, both our Spring Lettuce, and that which you are to replant again at the latter end of April and at the beginning of May, viz. the Curled bright Lettuce, and the Royal, and Bellegarde Lettuce, the Perpignon Lettuce which is greenish, the Alsange, the Chicons, and the Green, Red and bright Genua Lettuces are near two Months on the Ground, before they grow big enough to be replanted. Sow also Cabbages for the latter Season, and Collystowers to plant them in their proper places, about the end of April and beginning of May; and if they come up too thick, take out some, and replant them in a Nursery, to make them grow bigger, &c.

Sow Radishes in the naked Earth among all the other Seeds that you are fowing, because they do no

harm there.

Sow Arach, or Orage, in the naked Earth.

About Mid-March, fow Citruls or Pompions upon

hot-Beds, to replant in the beginning of May.

Make an end of pruning and planting during the course of this Month of all Garden-Trees, and also of Goeseberry, Curran, and Raspberry shrubs, &c. It is very convenient to delay the pruning of vigorous Trees 'till they begin to sprout, as well to let them spend their first Strength, as to prevent losing any of their Fruit Buds which we cannot 'till then discern,

and

250 The Compleat Gard'ner. Vol. II.

and which come to their perfection in the Spring-Seafon.

Take up at the beginning of the Month, with Mold and all, the plantation of Strawberries, which you had in the Nurfery, to form Cold Beds and Squares of them to remain and to refurnish those where there want any.

Sow fome Seed of Pierce-pierre or Garden Sampbire in fome tub of Earth, or in the naked Ground in fome

shelter'd place.

Sow a third time a few more Peas, of the great

fquare fort.

At the very beginning of the Month fow a little quantity of Endive very thin, to have some of it

whited about Mid-summer.

Towards the end of the Month, or at the beginning of April, fow a little Cellery in the naked Earth, to have fome late in the Months of August and September. Cellery is commonly almost a Month a coming up; and we sow a little of it at the same time on a

Hot-bed, in order to have some of it early.

Begin now to uncover a little your Artichoakes, but we feldom begin to minure them till the full Moon of March be past, which is generally very dangerous both to them and to the Fig-trees, which last must not yet be quite uncovered, it being enough to do it half way, at the same time we take off all their dead Wood and Branches, whether killed by the Frost, or by any other means.

About the middle of March, or before if the weather be mild, begin to fow some Red or Golden Pursulain upon bot beds under Bells and continue still to

Tow of the Green fort.

We replant in their fixt places common Cabbages and Millan Cabbages, which you should take care to have ready in your Nursery, from the beginning of November last past, in some well shelter'd place, but replant

replant none of those that begin to mount, that is, to run up their Stalks, as if they were going to Seed.

Plant the Asparagus Squares which you have occasion for, to which purpose make choice of a fine Plantation of one years growth, or elfe of one of two.

The way to plant A/paragus is, to place two or three Plants of them together, and neatly to fpread out their Roots without cutting them but very little, and then cover them with a layer of Earth of two or three Inches thick, to plant those Tufts Checquerwife, at a Foot and a half distance one from the other.

This Cold Bed should generally be full four Foot broad, that there may be room enough for three ranks of them. But if you defign to force any of them by heat in Winter, you must make the cold Beds but three Foot broad, and observe if the Ground be dry, to lay the Bed hollow within the Earth with a good Spade, and by that means raife the Paths Arch-wise, making use of the Soil that comes out of it, to cover again by little and little, and year by vear, the Plantation as it grows stronger, and rifes out of the Ground. But if it be a moist Ground. and very cool, it is better not to make the Bed fo low nor hollow, but on the contrary to keep it a little higher than the Paths, that the Winter waters may descend out of it into them, and may not rot the Plants, to which nothing is more dangerous than too

Afparagus both old and young must be carefully howed or cleared of Weeds, and in this Month of March, before they appear above Ground, you must afford them a little manuring, by turning up the Earth to the depth of half a Foot about them, to give the young Asparagus the more liberty to shoot up.

At the beginning of the Month it will be time to replant what you have a mind should run to Seed, vis. Leeks and Onions, and especially the white fort, Cloves 252 The Compleat Gard'ner. Vol. II.

of Garlick, Cloves and Seeds of Shallots, white Cabbage, Pancaliers Cabbage, &c. Now likewise you are to tie up such Lettuce as should Cabbage, and yet do not, which tying makes them in a manner Cabbage

by force.

Sow the Seed of Panacht, or striped Gillyslowers upon Hot-beds, before the full Moon, to replant them in May; sow also the Anual Flowers upon Hot-beds to replant at the latter end of May, viz. Passe velours, or Velvet Flowers, called also Flower gentiles, and Amaranthus, Indian Occilius, or French Marygolds, Indian Roses the Belles de Nuit.

Set in the Ground, Almonds that have sprouted,

breaking off the fprout before you plant them.

Sow in the Flower Pots, or Parterres, some Seeds of Poppy, and of Larks Heels, which will flower after them that were sown in September.

Provisions and Products of March.

E have now upon our Hot-beds, abundance of Raddishes, and little Sallets, and of Screel, and Cabbage Lettuces, under Bells, which are the bright carled Lettuces fown in November and December, and afterwards transplanted into other Hot beds. The other forts of Lettuces will not come to any thing under Bells.

We continue to have forced Asparagus.

As to Flowers, if the Cold be not extraordinary violent, we have every where, and that naturally, all those forts which blow only in good Expositions in the preceding Months, beside which, we have Violets, Fachinths, Passe-touts, and single Anemonies.

And towards the end of the Month, we have En-

And towards the end of the Month, we have English Narcissus's, Narcissus's of Algiers, English Iris, or Flower de-Luces, yellow Stock-Gillishowers, None such Narcissus's, single and double Fleapatica's, as well of

the

the Red, as of the pale Violet Sort, Hellebore Flow-

ers, some fingle Junquils.

We need not now force any Flowers, unless it be fingle or double *Junquils*, if the Weather be very hard.

But if the Weather be very mild, we have double Anemonies, Bears Ears, Fritillarias, some Spring Tulips, Daifes, Hammes, or Fleam-flowers, Persian Iris, and Junquils at the latter end of the Month.

How to judge certainly by viewing and visiting a Kitchen Garden, whether there be any thing wanting in it, which it should be stock'd with in March.

N March, if your Ground be great, and the number of Labourers proportionable, you should have the pleasure with one cast of an Eye to see them digging, making up, sowing, planting, howing, weeding, graffing, pruning, &c. for in sine, before the Month be out, the most part of the Ground should be taken by either with Seeds or Plants, which are to serve for provision for the whole year. All that which was before coverd with Dung, ought to be discharged of its coverings which are now grown noisome, as soon as they cease to be necessary, and every thing ought to breath the free Air, which begins now to cheer both Animals and Plants; you should at this time have at least something to begin to gather, either of Sallets or Raddishes, of the new Season.

Here is no Month in the year wherein there is more work to be done in Gardens than in this, for now the Earth begins to be very fit, not only to be manured, but to receive whatfoever you have a mind to plant or fow in it, as Lettuce, Leeks, Cabbage Borage, Bugloss, Artichoaks, Tarragon, Mint, Violets, &c. Before the Month of April, it is as yet too cold, and after April it begins to be too dry.

Perform now your fecond pruning of the Branches of Peach-Trees, I mean only the Fruit Branches in order to cut them off short to that part just above where there is Fruit knit; and if any of those Peach-Trees, have produced any very thick Shoots upon high Branches, as fometimes it happens after the full Moon of March, pinch them to make them multiply into Fruit Branches, and to keep them low, when there is occasion, that they may not run up too high before

Continue to trim Musk Melons and Cucumbers, to new heat your hot Beds, and make new ones, and to fow Cucumbers, that you may have fome to replant that may ripen about the end of Summer, and beginning of Autumn.

Make some hot Mushroom Beds in new Ground, the manner of doing which I have already described

elsewhere.

'Tis the Moon of this Month, that is vulgarly call'd the Ruddy Moon, it being very subject to be windy, cold, and dry, and to be fatal thereby to many new planten Trees, unless great care be taken to water them about the Foot once a Week.

Weed up all the ill Weeds that grow among good Seed, take the same course with Strawberries, Peas, and replanted Lettuce, and howe all about them the better to loofen the Earth, and open a passage

for the first Rain that shall fall.

About the middle of April begin to fow a little White Endive, in plain Ground, to whiten it in the fame place; and provided it be thin fown, no Seed comes so easily up as this fort of Endive.

At the middle of April fow also in their places, the first Spanish Cardons, and the second at the beginning of May; the first are commonly a Month in com-

ing up, and the other about fifteen days.

Also still sow in this Month, some Scrrel, if you be

not sufficiently provided with it before.

As to what is to be done to Melous in this Month, we refer you to the discourse on that Subject, Page

Choose a part of the fairest of the Cabboge Lettuces, as well as the Winter ones, which are the Shell and Ferufalem Lettuces, as the Curled Bright Lettuce raifed up Hot Beds and under Bells to plant them all together in some cold Beds at a foot distance one from another, to let them run to Seed; which is also perform'd with a planting Itick.

Plant edgings of Time, Sage, Marjoram, Hyssop,

Lavendar, Rue, Worm-wood, &c.

Replant Spring Lettuce to Cabbage, which fucceed one another in this order; the Curled Bright Lettuce is the first and best, as being the most tender and delicate, but it requires a mild and light Soil, or above all, a Hot Bed to plant it on, and Bells, from the Month of February, and during all the Month of March, and the beginning of April. A gross Soil agrees not with it, for instead of growing bigger there. it dwindles to nothing.

The Green Curled Lettuce, the George Lettuce, the Little Red Lettuce, and those called the Koyal, the Bellegarde, and the Perpignon, follow next after. The Royal Lettuce is a very fair and thick Lettuce, which

differs

differs only from the Bellegarde in that it is a little less Curled. The Capucin, Short, Aubervilliers, and Austrian Lettuces succeed them, and run not so easily to Seed, as the preceeding ones. The Alfanges Chicons, and Imperials, which are all Lettuces to tie up, bring up the Rear; and the Genua Lettuces, both the Red, Bright, and Green, are the last Summer Lettuces; you must replant a good number of them at the very beginning of May, to have them good about Midfummer, and all the rest of the Summer; of all Lettuces, this fort best endures the great heats, and is least disposed to run to Seed; for which reason to obtain Seed of it, you must have sown it upon Hot beds from the very Month of February, that you may have some good Plants of it to fet again at the latter end of April. .

The Royal Lettuce begins again to be fit to be replanted about the middle of September, to supply you, together with that of Genua, all the rest of Autumn.

From the end of August begin to sow the Shell, of Winter Lettuce, that you may have some fit to replant in the Months of October, and November, for our Winter provision.

The Aubervillier Lettuce grows fo very hard that it is scarce fit for Sallets, but is better for Pottage; but

yet it is very subject to be bitter.

You must not fail every fifteen days, to sow a little Genua Lettuce, that you may always be provided with some fit to replant during all the whole Summer, 'till the middle of September.

If the Ruddy or dry Winds Reign, as they generally do this Month, we must carefully and plentifully water every thing in our Kitchen-Garden, except it

be the Asparagus.

Now likewise search the Woods for Young Strawberry Plants, to make Nurseries, in some part of your Garden, plant tusts of two or three plants of them together, at sour or sive Inches distance one

from

Vol. II. The Complete Gard'ner. 257

from another, and if the Soil be dry, in a hollow Bed of two or three Inches deep, the better to retain and preserve the rain water, and that of our waterings.

We also now dif-eye or separate the Off-sets or Slips of our Artichoaks, as soon as they are big enough, and we plant as many of them as we need, two or three of them in each hole, or Trench of about three or four Inches deep, and two full foot and a half distance one from the other, each Bed should be four foot wide, and contain two rows as Artichoak Plants along its sides, and there must be a void space left in the middle, of three Foot wide for the planting of Leek Chards, or great whited Leeks, or else of Colly-showers, in imitation of the Market Gard'ners, who are good Husbands of their Ground. The two Artichoak Plants which we set in each hole, must be placed a full foot and a half distance one from the other.

We have already in the Month of March, set into the Earth, those Almonds which sprouted early, and in this Month we set those which having not sprouted at the same time with the others, had been put up

back again into Mould, Earth, or Sand.

In the beginning of the Month, Gardens should be almost in their Perfection; we must sow Parsly, wild Endive, or Success, and the first Harice's or French Beans, the second being to be sown about the middle, and the third at the latter end of May, that so we may have a crop of them about two Months after sowing.

About this time the Strawberries growing in the naked Earth, shoot forth their stems, when we must take exact care to pluck all the Cuckows among them, that is, those Strawberry Plants that blossom much

without knitting.

We fow our last Cucumbers about the tenth or twelfth of this Month, to have some lateward ones and such as may be fit to pickle in October, which last

ar

are commonly called Cornichons, or horned Cucumbers,

and in English, Crumplings, and Guerkings.

It is particularly about the end of this Month, that May Moon begins, that is too fertile, and so vigorous in its productions, when we must with all possible care run over our Wall trees, and draw from behind the Trails, those Branches that grow between them and the Wall, as well the smaller ones, as more particularly those that are thick; at the same time Peach Trees and other Stone Finit Trees are to be pruned the third time, it having been done the second time whilst they were in Blossom, to take away all those Branches that had not blossom'd.

At this time likewise, we are to pinch that is to fay, break off to four or five Eyes or Buds, those thick shoots in Peach-Trees that are sprung out since the main Pruning of that year, in order to make them shoot out three or four midling shoots, one whereof may be for a Wood Branch, and the rest for Fruit; this Operation is to be performed particularly upon those very thick Shoots that spring out of the Extremity of a Tree that is grown high, when it has already attained its due height.

Provisions and Products of April.

E have now abundance of Radishes, Spinage and Sallets with their Furnitures, and other edible Herbs.

We have likewise at the very beginning of the Month, bright curled Cabbage Lettuces, if we have taken care to raise any upon hot Beds, otherwise we have none, for the Winter Lettuces are not, as yet, cabbaged.

Also at the very beginning of the Month we have some Strawberries by the extraordinary help of our

Vol. II. The Complete Gard'ner. 259

hot Beds, and Glass Frames, if we have had the Wills or convenience to make use of them.

Also Asparagus produced naturally and without Artifice.

Likewise an infinite number of Flowers, as Anemonies, Ranunculus's or Crow foots Imperials, Narcissus of Constantinople, English Narcissus, and Algier's Narcissus, white Narcissus, Prim-Roses, Violets, Hepatica's, both red and pale blue, and about the end of the Month we have fair Tulips.

How to judge certainly by viewing and visiting a Kitchen-Garden, whether there be any thing wanting in it, which it should be slock'd with in April.

Nithe Month of April, we are not to find any thing new to be done in our Kitchen-Gardens, unless it be an Augmentation of hot Beds for Musk-Melons and Cucumbers. The Earth in them should now be covered almost all over with a new decoration of Insant Plants; Here we should see Articheaks rising as 'twere from the dead, and there Asparagus piercing the Ground in a thousand places; here we should with pleasure observe the Cabbage Lettice wind up it self into round Balls, and here that a multitude of Green Herbs, and Legumes, so different in colour, and various in their shapes; Jacinth, the Tulip, the Anemone the Ranunculus, and so many other Flowers,

Works to be done in May,

IN the Month of May, it is that the Mother of Vegetation feems in carnest to display and exert all the force she is Mistress of, in order to the maintain-T 2

ng her self in that flourishing Estate during the whole Months of June and July following, at this time covering the Walls with new Branches, plumping the Fruit, and covering the Earth with a lovely and charming verdure, &c. And now our Gard'ners have great need to be upon their Guards, to prevent their Gardens falling into disorder, because 'tis most sure, that if they be not now extremely careful and Laborious, there is no disaster but they may expect; pernicious Weeds will in little time choak up all their good Seeds, their Walks and Alleys will be overgrown, and their Trees will fail into the greatest Confusion, for which reasons it will highly concern them to be extremely watchful and diligent to weed, manure, cleanse, to take off all superfluous Leaves and Sprigs, and to nail up Wall Trees, by which means it will be in their Power to acquire the defirable Commendation of having adorned and fet out their Gardens with all the lustre and excellency which they ought to have.

Green Peas, that were fown in Banks or Borders in October, do begin to recompence our Pains, and to blossom at the coming in of this Month: About the feventh or eigth day of this Month, we should plant our Collyflowers, Milan Cabbages, Capucin Capers, or Nasturces, Beet Chards, &c. If we plant them somer, they commonly run to Seed, which is to be avoided; and in fine for those things, we ought not to pass the fifteenth day, nor likewise for the sowing Winter Cabbages. We now make all the haste we can, to make an end of dif-eying or flipping our Artichoaks which are vigorous, and seem to have need of being discharged and thin, and make an end of planting new ones. The Eyes or Sucker-slips are good enough, provided they be pretty thick and white, though they have no root at their heel or foot, and we may be fure to have very fine Fruit from them n Autumn, and in truth it were to be wished, they would

would yield none fooner, because those produced before that time, are commonly pitiful, starvling, and as 'twere abortive Fruits. Yet 'tis not enough to plant only fome good thick young flip-fuckers, but we must likewise plant some midling ones, especially in some well shelter'd place, only to fortifie themselves there during the rest of the Year, that they may be able to yield as their first Artichoaks, next Spring; those which have born in Autumn, not making fuch swift advances as these other. Next we are to plant our Beet Chards almost at the same time, which are well placed, if planted in the middle of the Artichokes, that is, one Beet plant between two Artichokes, so that there may be some in one Rank. and none in the other, for there must be room enough left free, to go upon to water, weed, manure, gather. and to cover them too, when need shall require.

We also at the same time rank our Fig-Trees in the place allotted for the Fig Plantation, that we may have them in the disposition we desire. They begin then to put forth their Leaves and Shoots, and at length

their Fruit begins to plump at the full Moon.

Towards the end of the Month, we begin with diligence and expedition, to nail up the new shoots of Wall-Trees, if they be strong enough to suffer it : And it is convenient to have finish'd this work at the beginning of June, because at the end of that Month we must begin the second nailing of the first Shoots. and the first of those which were never yet nail'd.

If there be any Trees designed to mount upright we must accordingly order for that purpose, the Branch

that feems most proper for it.

We low a great deal of Genoa Lettuce, and we replant some of them, and of the other Lettuces also.

We Likewise trim Pear-Trees, either to take off the falle Shoots if any appear, which is done by plucking them quite away when they make a confusion, or even fuch

T2

262 The Complete Gard ner. Vol. II.

fuch others which though they be good, yet because they might produce that confusion which is so much to be avoided in a Tree, must therefore be taken off, for the better fortifying of those that are to make the

figure of that Tree.

Sow Endive, that you may have some good, at the end of July, which may be whitened in the same place where it sirst grew, without removing if it be sown thin, and well watered during the whole Month. Take now also the advantage of some rainy Weather, to plant in their designed places, your annual Flowers some of them seldom sailing to come to good there; likewise take the advantage of the same time, to sill up with Basketed, or Circomposed Trees, in the places of those that are dead, or that thwattyour expectations, or that give no very good hopes of their thriving. It is necessary to water these Trees two or three times during the rest of the Summer.

Also still plant Beet Chards, choosing for that purpose the brightest of those that are of the growth of the last sown Seeds, as being both fairer and better than

those which are green.

Continue your Nurserie, of Strawberrie Plants 'ill the end of this Month, at which time you may perfectly difflinguish the good onesby their Stems, or upright Shoots.

Also continue to tie up those Lettuces that do not

Cabbage as they should.

Sow no more Lettuces, except Genua Lettuces, after the middle of May, because all the rest but only this

last fort are too apt to run to Seed.

Replant Musk-Melons and Cucumbers in the naked Earth, in little Holes or Trenches filled with Mould; also plant Pumpions or Citruls in the like holes, at the distance of three Toises, or Fathoms, they should be such as have been raised on Hot Beds, and therefore to make them take Root again the sooner, cover them with something for five or six days, unless it rain, the great

heat

heat of the Sun, otherwise being apt to make them

wither, and sometimes to kill them quite.

Continue to fow a few Peas, which must be of the biggest fort: and if you think good, pull off some of the Branches of the others that are over vigorous, after they are well cleared of Weeds: Peas that are disbranched, bearing a more plentiful crop than others.

Bring out your Orange-Trees at the first quarter of this Months Moon, if the Weather begin to be secure

from the affaults of the Frost.

Trim your fasmins when you bring them out, cutting off all their Branches to the length of half an Inch.

At the end of this Month, begin to clip for the first time, your Palisades, or Pole-Hedges of Box, Fila-

ria's, Yew, and Especia's.

Above all things, care must be taken to water all your Plants largely, or else they will roast and scorch, whereas by the help of seasonable waterings, you may visibly perceive them thrive. Also now water new planted Trees, and for that purpose make a hollow Circle of four or five Inches deep, round about the extremitie of the Roots; and pour into it some Pitchers of Water, and when 'tis soak'd in, either throw back the Earth into the Circle, or cover it with dry Dung, or Litter, in order to renew your watering several other times, 'till the Trees have taken saft root again, after which, fill it with Earth again.

You may begin to replant your Purstain for feeding

towards the end of the Month.

Continue to trim Musk Melons, but replant no more of them after the middle of May.

But still continue to plant Cucumbers.

About the end of the Menth, begin to plant Cellery, and you may use two ways of planting it, viz. either in Cold Beds hollowed into the Ground, as you

r₄ do

264 The Complete Gard'ner. Vol. II.

do Asparagus, planting three ranks of them in every Bed, and placing both the Ranks and the Cellery Plants at about a Foot distance one from another, and that is the best way for them when they are a little bigger than ordinary, that so you may be able to raise the Earth about them afterwards, with that which was taken out of the Furrows, and which was thrown upon the next Cold Beds, or else replant them on plain Ground at the same distance as before, and at the end of Autumn, binding them first with two or three Bands; these are raised in Tusts, that you may replant them as nigh as you can to one another, that so they may be the more easily cover'd with long dry Dung, and the better whitened and defended from the Frosts.

Towards the end of the Month begin to tie your Vines to their Props, and to nail up such stocks of them, as are planted by Walls, after you have first clear'd them of all their feeble, unprofitable, and un-

fruitful Shoots and Sprigs.

Likewise plant single Anemonies, which slower a Month after, and you may have planted some every Month since the last preceding August, they blowing and slowering in the same manner, if not hinder'd by

an extreme cold Seafon,

At the very beginning of the Month, or at least as soon as ever you can, pick off and thin your Apricots when there are too many of them, never leaving two close together, that so those you leave on may grow the bigger; and at the end of the same Month, you may pick off and thin your Peaches and Pears, if they be big enough, and there be too many of them. About that time also or at the beginning of the ensuing Month, the first bright Cabbages are to be sown for Autumn and Winter, the biggest of them which are replanted in July, being to be eaten in Autumn, and the less vigorous, which are replanted

Vol. II. The Complete Gard'ner. 265 in September and October, being to serve for our Winter Provisions.

Continue to fow a few Radifhes among other Seeds, as you should have also done in the two last precess

ding Months.

If your Garden be fituated in a sandy and dry Ground endeavour by the help of some little Dykes or Gutters to carry off all the water that falls sometimes in hasty Storms to those places that are manured, that none of it may be unprofitably wasted in the Walks or Allies, and if they be situated in Ground that is too strong, sat and moist, drain it away from those Grounds that are incommoded by it, by conveying it into Walks or Allies, to spend it self there, or shooting it off into Stone Gutters that carry it out of the Garden; for which purpose you must raise your Ground into arch'd ridges.

During all this Month, it is good to lay yellow flock Gilliflowers, by planting Cuttings of them, whereever you have a mind, or by laying their Branches that

still grow to their Plants.

You should likewise replant before the end of May some green curled and Aubervilliers Lettuce, that you may have some all the Month of June, together with the

Chicons, and Imperial Long-Lettuce.

You must also at this time endeavour to destroy the thick white Worms, which now spoil the Strawberries and Cabbage Lettuce, and take away the green Caterpillars, which quite eat up the Leaves of the Curran and Gosseberry bushes, and so spoil their Fruit.

At the end of May, you should also thin those Roots that grow too thick, and replant those you have plucked up in another place, as Beet raves or Red Beet-

Roots, , Parsnip, &c.

Provisions and Products of May.

T is now the time of the flourishing reign of all Verdures and green things, and of Sallett, Radishes, Asparagus, and Cucumbers as to their plenty and abunnance. Peas and Strawberries now begin to come in, and you may and ought to have of those forts of Long Lettuces call'd Allanges, and white Chicons, provided you have had timely care to raile some upon Hot Beds and early to transplant them, either in other Hot Beds, or else in the naked Earth, in some well exposed place.

You have also an infinity of all forts of Flowers, Tulips, Stock Gilliflowers of all colours, Prim rofes both deep blue and pale blue, Musaris, Daisies, Flames, Spring Honey Suckles, Roses of Gueldres, Single Anemor

nies, &c.

Likewise both single and double Narcissus's, and Peonies both of the Flesh or Carnation, and of the very red colour.

Now you begin to have some Spring Larks Heels.

You may have the Flower of the Trifolium Arboreum, or yellow Trefoil, growing on a Shrub, and both the Common and Persian Liac, Mary golds, and Sedums, otherwise called Palmaria, and Musked white Rock Gills flowers, both fingle, and double, that is to fay, the Julians. As likewise Columbines, Veronica's, or Fluellins, plumed or panached Fazinth, yellow Martagons with their Flame coloured Pendant, Spanish Carnations, Co.

How to judge certainly by viewing and visiting a Kitchen-Garden, whether there be any thing wanting in it, which it should be stock'd with in the Month of May.

THEN May comes in we have no longer occasion to demand why such and such spots of Ground are yet bare, Spanish Cardons, Gollystowers, Chard beets, Cellery, and even Artichoaks, and Cabbage Lettuces, which were not to appear to early, and for which those places were design'd, coming to occupy them at the latter end of April, or beginning of this Month, and Purstain which because of the delicateness of its temper, had 'till now been retain'd in the Seed Closet, comes out at this time to gild the Earth, and to offer it telf in abundance to pleasure its Master. The Stramberries beginning to come now to Maturity, open and lead the way to the other Red Fruits, which are immediately to follow after them: Green Peas are ready to satisfie the longing Appetite of the lickerish Palate: There is hardly any but Spinage, and Maches, that stave off the performance of their duty 'till August and September, for we may now see some little beginnings even of Endive, and if Hasting or Early Cherries were the first Fruit that appeared in this Month of May, the Hasting Apricots, the little Muscat Pears, and the Avant Peaches, or Forward Peaches, will not leave them long alone to enjoy the glory of being the fole Riches and Ornaments of our Gardens.

Works to be done in June.

N June, plant Leeks in Holes or Trenches, fix full Inches deep, at half a Foot's distance one from the other.

Continue to faw Endive, and Genoa Lettuce, that you may be furnisht with some to replant upon occasion all the rest of the Summer.

Replant Beet Chards in order to have them good to eat in Autumn, they are best placed in the void space remaining between the Artichoak Ranks, they must be set at the distance of a Foot and a half one from the other.

Take great care to excirpate all the Weeds which now grow up in abundance, and that particularly before they run to Seed, to prevent their multiplying, which they are apt to do too much of themselves, without sowing.

Now without delay, clip all your Palisade's, and edgings of Box, so that they may be all surnisht at farthest at Mid Summer, and have time to shoot out again before Autumn; now you must liberally water all Seeds sown in your Kichen Gardens.

Water plentifully, every day the Cucumbers upon Hot Beds, and Musk-melons moderately two or three times a week, allowing half a Pitcher full of water to each Plant.

From the middle of June begin to graff by Inoculation, your Stone-Fruit Trees, and especially Cherries upon great Trees, upon Wood of two Years growth, which are cut off three or four Inches from the place where the Scutcheon is to be placed. The best time for this is always before the Soffice.

Gross Soils must be often stirred and manured, that they may not have time to grow hard, and chap, commonly we bestow an universal manuring or stirring up the Ground upon all our Gardens in this Seafon, and the best time to stir dry Grounds in, is either a little before, or after Rain, or even whild it rains, that the water may more swiftly penetrate the bottom, before the great heat comes to turn it into vapours, and for strong and raoist Soils, we must wait for hot and dry weather, to dry and heat them, before we move them; careful Gardners make Dykes to convey the gluts of Water that sall about this time in hasty Storms, a cross their Squares, especially if their Ground be light; but on the contrary, if it be too strong, they drain the water out of the Squares, as I have said already, when I was speaking of the works of May.

Carefully cultivate your Orange-Trees, according to the method prescribed in the Treatise composed pur-

posely on that Subject.

Take up Tulip Roots out of the Ground at the end of this Month, their Leaves being then withered.

Disbranch Harico's or French Beans, and towards the end of this Month, fow Peas to have them fit to eat in September.

Provisions and Products of June.

Fruits, as Strawberries, Currans, Goofeberries, Cherries and Bigarro's or Heart-Cherries, &c,

Some Pears, and particularly little Muscats.

Abundace of Artichoaks and Beet-Chards.

Great store of Peas, and of Garden, and French Beans.

Great flore of Mushrooms and Cucumbers.

Also great plenty of fine, or sweet and strong scented, or Aromatick Herbs, viz. Time, Savory, Hyssep, Lavender, &c. And also of Medicinal Herbs.

Roman

270 The Complete Gard'ner. Vol. II.

Roman Lettuces, and white Alfange Lettuces, and a-

bundance of Genua Lettuces, and Purstain.

Abundance of Flowers, as well to garnish Dishes, as to set out flower Pots, viz. Double Poppies of all colours, white, pale, violet, slish colour'd, or Carnation, slame coloured, purple, violet colour'd, and panached or striped yellow, and violet Pansies, Larks Heels, Julians, Fraxilenes, or Fraxinellas, or Bastard Dittanies, Roses, of all sorts, viz. double, panached or striped, double Egiantines, or Dog-roses, Roses of Gueldres, Cinnamon Roses, white Lillies, yellow Lillies, Matricaria's, or Feather sews, Asphodel or Asphondel Lilies, Calves snouts, Virga Aurea, or Golden Rod, of Jasse Flowers of two colours, Gladiolus's, Veronica's, or Fluellines, Spanish Carnations, Mignards, Verbascums, or Mullein Flowers, double Coqueriers.

Thiaspi, or Treacle Mustard of two sorts, the great and little Muscipua's Valerians, Touse Bonnes, or Agoods, or good Haries, Poets Gillistowers, both the white an Carnations, yellow Willow Herbs, or Loose-strifes, Lady-Gloves; and towards the middle of June, Roman Chervil, Orange Flowers, Tuberoses, single Anemonies, Mig-

mardises, and Marine or Sea Violets.

And you begin to see tome Cabbages.

How to judge certainly by viewing and visiting a Kitchen-Garden, whether there be any thing wanting in it, which it should be stock'd with in the Month of June.

HE parching heat of the Month of June hinders us indeed from going into our Garden in the heat of the day, but what charms are there not, in going to visit it Morning and Evening, when the cool breathings of a gentle Zephyr reign there with

Sove

Vol. II. The Complete Gard'ner. 271

Sovereign sway? Now is the Season when we may visibly perceive with our Eyes, all things to grow and thrive, and see a Branch that five or six days before, was not above a foot long, now shot out to three or four. Leeks are now planted, and squares covered with green Herbs, complete the Tapestry that adorns the Ground; the Vine Flowers make an end of throughly embalming the Air, which was already over perfum'd with the grateful odour of the Strawberries.

We gather in all parts, and at the same time with profusion distribute all those Plants that are become so beautiful and accomplished; we fill up the places again we had disfurnish'd, so that there hardly ever remains any part void; and nature now affects no better divertisement than to be amazing us with Miracles of fertility, fo well affished as she is, by the kindly warmth of the Father of Light; only the needs now and then the Auxiliary refreshment of convenient moisture, moiflure which the propitious Clouds sometimes abundantly pour down, but which sometimes the Gard'ners Industry too is fain to supply her with in the time of need. The Cold Beds and Counterborders levelled and adjusted even to a Line, and well turnisht with Gabbage Lettuces; the forest of Artichoaks of different colours which now appears, is not less admirable than the Palisades and Pole Hedges to exquisitely well extended.

Works to be done in July.

IN this Month, many forts of Seeds are gathered, and Endive is fown for the provision of Ausumn and Winter. We also sow Royal Lettuce to have it good for use at the end of Autumn.

Still continue to fow fome Cibaules and white Beets for Autumn, and fome few Radishes in cool places, of

272 The Complete Gard'ner. Vol. II.

fuch as are extremely well water'd, to have them fit

to eat at the beginning of August.

If the Season be very dry, begin at the latter end of the Month, to graff by inoculation of a Dormant Bud, upon Quince Trees, and Plum Trees.

Begin to replant White or Bright Cabbages for the

end of Autumn, and the beginning of Winter.

Sow more Lettuce Royal.

Sow for the last time, your Square Peas in the middle of July, that you may have some to spend in October.

In this Month particularly, Peach Trees produce feveral shoots. About the middle of July, begin to lay your Clove Gillyslowers and Carnations, if their Branches be strong enough to bear it, otherwise you stay 'till August, or the middle of September,

Provisions and Products of July.

E have in this Month abundance of Artichokes, Cherries, Griots, or Agriots, and Biggarro's or Heart Cherries.

Plenty of Strawberries, Peas and Beans.

Great store of Cabbages, Muskimelons, Cucumbers; and all forts of Sallets.

Some white Endive. and some Radishes.

Some Plums, viz. the yellow Plum, and the Cerifer, or little Cherry-Plum.

Some Summer Calvil-apples.

A great many Pears, viz. Maudlin Pears, Cuisse Madams, or Lady Thighs, great Blanquets, or great White Psars, Orange green Pears, &c.

About the middle or latter end of July, we have

the first Figs.

Also we have Verjuice,

As for Flowers, we have still a great many, and the most part of them I have mention'd in the preceding Month.

Vol. II. The Complete Gard'ner. 273

We have besides them, Geranium Necteolens, or-Night smelling Crane bill, Rue with its Olive-colour'd Flower, Jerusalem Cresses, both single and double, Kidner-Beans, of a flame colour, which last till November, Cyanus, or Corn Flowers, both white, and pale, violet, Capucins, or Nasturces, Camomils, and towards the middle of July, Clove gillissowers and Carnations begin to come in.

Works to be done in August.

ROM the very middle of August, you must begin to sow Spinage to be ready about the middle of September, and Maches for Winter Sallets, and Shell Lettuces, to have Provision of Cabbage Lettuces; at the end of Autumn, and during the Winter Season.

Replant Strawberry Plants in their designed Places

which you have railed in Tufts.

At the latter end of the Month, sow some Cabbage in some good Exposition, to remove into a Nursery, in some other well sheltred place, where they are to pass the Winter, in order to be replanted in their designed

places in the following Spring.

Also sow all the Month long some Cabbage in some good Exposition, as well to replant at the end of September or beginning of October, in the places where they are to remain under some good shelter, as to have some ready hardned against the cold, to replant again after Winter, either in the naked Earth in the Month of March, or upon hot Beds, at the very beginning of February, if the Winter be very cold, they must be covered with long Litters

Sow Onions to have good ones the next year, at the very beginning of July, which should be replanted in

Marsh next following.

- W

274 The Complete Gard'ner. Vol. II.

We replant a great deal of Endive at a large foot distance between Plant and Plant, as also Royal and Perpignan Lettuces, which are very good in Autumn and Winter.

Sow Mâches for Lent.

Continue to nail up your Wall-Trees, and by little and little, to uncover those Fruits, which you would have tinged with much Red, as Peaches, Api-Appeles. &cc.

Tye up your Endive with one, two, or with three bands if it be very high, but the upermost Band must be always looser than the rest, otherwise the Lettuce will burst in the sides whilst it is white-

ning.

At the middle of August we begin to cover with compost, the Sorrel that was cut very close to recruit its vigour, a good Inch thickness of Compost is enough to strew all over it, because they would be apt to rot

if you should use more to them.

Pluck off the runners of Strawberry Plants, to preferve their old Stocks in the greater vigeur, and when their Fruit is past, which is about the end of July, or the beginning of August, cut away all the old Stems, and old Leaves, that they may produce new ones.

Still continue sowing of Spinage, for the beginning

of Winter.

Take your Onions out of the Ground as foon as their Stems begin to dry, and let them lie ten or twelve days a drying in the Air, before you lay them up in your Granary, or some other dry place, or else bind them up in Ropes, because otherwise they would ferment and rot, if they were laid up before they were dry.

Gather your Shalor at the very beginning of the Month, and draw your Garlick out of the Ground.

Vol. II. The Complete Gard'ner. 275

At the end of August the Florist's set into the Earth their Facinitis, fair Anemonies and Ranunculus's or Crow-

foots, Junquels, Totus Aibus's and Imperials.

At the beginning of this Month, tread down the stems of Onions, and the Leaves of Beet raves, or Red Beet Roots, Carries, Parlings, &c. or else we take off their Leaves quite, to make their Roots grow the bigger in the Ground by hindring their Sap from spending it self above Ground.

Provisions and Products of August.

E have at this time abundance of Summer Pears, and of Plums, and of some fort of Peaches, as Maudlin, Minion and Bourdin Peaches, &cc.

As also of white Endive;

Plenty of Figs.

Great store of Musk-melons and Cucumbers.

We have also some Citruls or Pumpions:

We continue still to have all forts of green Herbs, all Kischen-Rooss, and Onions, Garlick and Shaloss, As allo

Abundance of Lark Heels, Indian Roses, and Indian Gillistowers, or French Marigolds, great store of Musked Roses, Monthly Roses, Jusmin, Latter Larks Heels, Tuberioses, Matricaria's, and greater or lesser Thiases's and besides them, Sun flowers, Asters, &C.

How to judge certainly by viewing and visiting a Kitchen Garden, whether there be any thing wanting in it, which it should be stock'd with in the Months of July and August.

IN these two Months of July and August, Kitchen-A Gardens should be so richly and happily endowed with whatsoever their condition is capable of, that we may find plenty of all things there both to fatisfie the pleasures of the present, and provide for the necefficies of the future time, to that let us require of them what we please, they may be as ready to answer, as we to make our Demands.

As for example, have we a mind to all or any forts of Herbs, Roots, Sallets, Perfumes, &c. They will immediately turnish us with them; have we a fancy to any Musk Melons? we may smell them a great way off and need but tollow our nofes, stoop and gather them; Would we have any Cueumbers, flat Pumpions, or other Pumpions or Citruls, Mustercems, &c. They will present us with store of them; Do our Appetites farther crave after Artichoaks, or Pears, Plums, Figs, &c. we may be fure to find there a confiderable quantity of all those things; or, Have we a mind likewise to have any Sweet and Aromatical Herbs, as Time, Sage, Savory, &c. or any relishing Plants. as Garlick, Onions, Ciboules, Leeks, Recamboles, or Spanish Garlick &c. There we need not fear to be supplied. Nay, the four or five next proceeding Months feem only to have laboured for these two latt, to that we may exspect all should go well in our Gardens in this featon, if we be provided with a good Gardner, and which above all thing, has the skill to class the and Judgment enough to know how and When the anther. The Carnations now are no fmall Columnitio our Gardens ; and the Flerifts now are

bulie

busie in couching their Layers, forget not to take their Bulbous Roots out of the Earth, to lay them up in places of shelter and security.

Works to be done in September.

Ontinue still the works of the preceding Month. Make hot Beds for Muffrooms.

Replant a great deal of Endive, but closer together now than in the foregoing Months, that is, place them at half a foot's distance one from the other, because

now their Tufts grow not fo large as before.

They must be replanted in almost all the spare places from the very beginning of the Months till the fiscenth or twentieth day. At the latter end of the Month, fow Spinage the third time, which will be good in Lent, and even until June following.

During this whole Month you must continue to remove Straw berry Plants out of your Nurseries, to reimplace those tusts which are dead in your Beds, you must immediately water them, as you must do all Plants

which are fet a-new.

Set some in Pots towards the twentieth day, if you

intend to force any in the Winter.

Tie up first with Ofier Withs, and afterwards towards the fifteenth of the Month, carefully wrap up with long Litter, or new Straw, some Spanish Cardons, and Artichoak Plants, to have them whitened or Blanched about fifteen or twenty days after; But great care must be taken in wraping them up, to keep them perfectly upright, otherwise they will overset, and fnap in funder on one fide; and to hinder the winds from lying them on our fide too, they must

be fenced with a Bank of Earth of about a full foot

From the fifteenth of the Month to the end, and till the middle of October, replant shell Lettuces in some well sheltered place, and especially near the foot of some Southern and Eastern Wall, that you may have some of them Cabbage for spending in Lene, and during the whole Months of April and May.

Bind up your Cellery with one or two hands below, and then raise a Butt or Bank about it either with very dry long Dung, or with very dry Earth to whiten it; but we must have a care not to tie it up but in very dry Weather, the same caution must be observed in all Plants that are to be tied, after which, cut off the extremity of the Leaves to prevent the sap from ascending and spending it self to no purpose, by which means it is kept down in the Buried Plant, and makes it grew thick.

Sow Maches for Lene, and for Reponces, it is not worth the while to fow them in a Garden, because there are enough of them in the Spring-Time, to be found

in the Corn Fields and by the hedge-fides.

Sow Poppies and Larks-Heels in Rower-Gardens, to have them Flower in June and July, before them that are fown in March.

Provisions and Products of September

TE have abundance of Vieles Peaches, Admirables, Purple, Perfick Peaches, &c.

Great store of Ruffet, or Ruffet Pears, melting Pears

of Breft, some Butter-Pears, &c.

Plenty of Endive, and of Succery, and of Cabbages. Towards the end of the Month begin to come in abundance of second Figs.

At the latter end of the Month we have likewise some Spanish Caordns some Articboke Chards, some Cellery

Cellery Plants, a great many Citruls, or Pumpions, store of Artichokes, and some Musk-melons still.

Some Colly-flowers.

We begin to have some good Muscas Grapes,

And some Oranges.

As to Flowers we have now great store of Tuberoses Asters, or Oculus Christi's, of Flower gentles, Velves Flowers, or Amaranthus, of Indian Gillissowers, or French Marigolds, ot Indian Roses, Marvels of Peru, Trilar Volubilis, Lawrel, or Bay Roses, both white and Carnation, Ultramarine Roses, Ordinary Stock-Gillissowers, both of the white and violet Sorts, &c. Ciclaments, and some Orange-Flowers, with single Anemonies.

Works to be done in October.

Ontinue the same Works as in the preceding, Month, except Graffing, the Season for which is now past but particularly you must be busic in preparing Cellery and Cardons, plant a great many Winter Lettuces, and some too upon old Hot-Beds, to force them so as to have them good for our eating about Martinmas.

Plant Winter Cabbages on those Stocks, lay aside all the Mold or made Earth, to use again when you make new Hot Beds, and carry away the rottenest Dung to

those Grounds that are to be dunged.

About the middle of October, carry back into their Houses your Orange-Trees, Tuberoses, and Jasmins, placing them there with some agreeable Symmetry, leaving the Windows open in the day, so long as it does not freeze, but keeping them always carefully shut at Night, till at last we shut them up quite and carefully dam up both them and the Doors V

Begin to Plant all forts of Trees as foon as their Leaves are fallen.

Continue still to Plant a great many Winter Lettuces in some well shelter'd Place, and on some good Borders, at six or seven Inches distance one from the other, there usually perishes enough of them to prevent our Complaints of their growing too thick together.

Towards the middle of October, the Florists Plans, their Tulips, and all other Bulbous Roots not yet let into the Ground.

In this Month you must perform your last manuring and turning up of strong, heavy, and moist Grounds, as well to destroy the Weeds, and giving an Air of neatness and agreeableness to our Gardens in this Sears son, when the Country is more visited than at any other time, as to make that fort of Ground timely contract a kind of Crust, that may hinder the Winter waters from so easily penetrating them, and on the contrary, may shoot them off down to places of a lower Situation.

It is convenient to begin to fow now in some well sheltered place towards the South or East, or else upon Hot Beds, those Sallers, &c. that are to be made use of in Winter, or early in the Spring: upon Condition that in due time they be well covered when swn, against the Cold.

Provisions and Products of October.

Plenty of Muscat and Chassela's Grapes.

Great store of Butter Pears, Doyennes, Bergamots, Vine-Pears, Lansacs, Crasans, and Messer-Johns.

Abundance of Endive and Success, Cardons, Areichoke Chards, Mushrooms, and Cucumbers, and still fome

some Musk-melons too, if there have been no hard

We have all manner of green Por Herbs, Sorrel, Beers, Cheruil, Parfly, and Cibouls, Rooss, Garlick, Onions, and Shalots.

Great store of Peaches, viz. Admirables, Nivets, White Andilies, Latter Violet Peaches, Tellow latter Peaches, Rambouillet, and Cadillac Pavies, Yellow Pavies, and Red Pavies

Spinage and latter Peas.

For Flowers we have fingle Anemonies, Tuberofe, Laurel, Time Flowers, Velvet Flowers, Jafmins, Laurel-Roses, Ciclamens, &c. and

How to judge certainly by viewing and vifiting a Kitchen-Garden, whether there be any thing wanting in it, which it should be fock d with in the Month of September and October.

YF in July and August our Kitchen-Gardens have fignalized themselves by their Musk Melons. Cucumbers, Legumes, and even by their Plums, their first Figs, and forme few Pears, &cc. we shall fee that in the Months of September and October which succeed them, they will Thew themselves exceedingly Glorious in the matter of Fruits which will be by the abundance of Peaches, Muscat, and Chaffela's Grapes, of lecond Figs, and of Ruffelet, Butter, Verte Longue, or Long Green, and Bergamot Pears, &c. This being undoubtedly the true Sealon for Fruits, and the time in the whole year wherein the Country is most frequented.

The moderate temper of the Air which now keeps an agreeable Medium between the great Heat of the Dog days newly past, and the bitter Cold that is to bring on Winter; Invites out the inhabitants of the Cities, to make a fally out to breath the free Air of nodinow

the

the Country, and to affilt at gathering of Fruits: And the Gardens ought now to surpass in an infinite quantity all they were accustomed to produce in other Months, nor is it fit now to suffer one speck of Ground to lie idle. For if any square has been newly disturnished, as for example, a Garleek, Onion, or Shallot Square, &cc. you should take care to fill it up presently again with Spinage, Mâches, Chervil, Ciboules, &cc. The same course is to be taken with some Beds of Summer Lettuces, which should be succeeded by a great number of Endive Plants, Winter Lettuces, &cc. The Bulbous Roots of Flowers must now be put into the Earth again, to begin to take such new Root as may desend them against the rigours of the approaching Winter.

Works to be done in November.

TN this Month begin to force an Artificial Spring by the means of your Hot Beds, upon which we fow little Sallets, viz. Small Lettuce to cut, Chervil, Cresses, &c.

Plant Lettuce to Cabbage, under Bells or Glass Frames, and replant upon them, Mine, Tarragon, and Balm Plants, and some Sorrel, wild Endive or Succery, and Macedonian Parsly, and Burnes, and if the weather still continue pretty fair, make an end of planting

Lettuces in places of good shelter,

This is particularly the Month of the greatest Work and Labour of all, in order to the avoiding the inconvenience of wanting Garden necessaries, which is no ordinary Companion in this dead Seaton, for in earnest the Cold fails not to make great Havock in the Gardens of the lazy; and therefore at the very beginning of the Month, how flatteringly fair soever the weather

weather appear, there must be some dry long Dung brought and laid near the Endive, Artichokes, Chard Beets, Cellery, Leeks, Roots, &c. that being ready at hand, it may with the more facility in sew hours be thrown upon every thing that needs 11, to prevent their destruction; and assoon as ever the Cold begins to shew it self, you must begin to cover your Fig-Trees.

Affoon as the Frosts appear, begin to ute the long Dung which you have been careful to order to be brought and laid ready in needful places; for example, if it be for Artichokes, you may keep them a little elevated towards the North, to ferve them instead of a small shelter, till you cover them quite; or esse if you be pressed with work to be done elsewhere, you cover presently, always taking care however before you cover them, to cut off all that is withered from them. A little of this Dung serves against the first attacks, but we redouble our coverings as the Cold augments. They which are not provided with that fort of dry Dung, may use instead of it, such dry Leaves as are gathered up in the neighbouring Woods.

If you have a mind to whiten for Chards any of the biggest of those Artichoke Plants, tie them below with two or three Bands, and then wrap them about with long dry Dung, or Straw, which you must bind over them again, as is already directed when we were

speaking of Cardons.

In dry Soils, you must earth up a little our Artichokes, which would be pernicious in wet Grounds, be-

cause it would rot the Artichoke Plants.

It is convenient to let the Artichokes alone so covered till the sull Moon of March be past, that being commonly very dangerous; and many Gardners suffer the less of their Artichokes, in being tempted by some sair days in March, to take off their coverings quite, and to proceed to manuring them; for if you uncover them, it should be but very little, and you should always have

the caution, to leave the Dung close by them, to be ready at hand to cover them again, in case the Frost

At the very beginning of the Month, before the Frofts be come, make an end of tying up your Endive that is big enough to fuffer it, and cover it with what you can get: you also cover your other Endive in the same manner, which we could not tie up. It likewife whitens equally well; and it is very convenient, if we have a confervatory, to plant as many as we can of the biggest of them there, in tutts, as we shall further shew hereaster, . . .

Now take the advantage of some fair dry weather. to lay up all you have a mind to keep for your Winters provision; and for that effect, take up the Plants in Tules, with Earth hanging to them, before they be Frost bitten, and plant them very close to one another in the Conservatory, which for Example are, all Roots, as Carrots, Parinips, and Beet-raves, or Red Beet-Rosts, and Artichoaks, which have Fiuit. The Green ones are more proper for this purpose than the Violet ones, which are more tender and less able to endure the Frost, and more apt to purifie in that part next their stem, than the other which are more rustical and hardy. And also Spanisto Cardons, Collystowers, and Endive or Succory, as well the White, as the Wild fort, and even Leeks and Cellery, though both these last will keep well enough in the naked Earth, when they are well covered: But here it is to be noted, that Cellery when once whitened must be eaten presently, otherwise it would rot; And you must be careful to raise some of it late, that is may remain small in the Earth, without being very much covered, which serves for the latter end of February and the Month of March.

Those Persons who live near the Woods, will do well to gather up the leaves there, not only to make use of for coverings, as I have said, but likewise to lay them to rot in some hole, the soil of them being very good, and especially to make use of for Mold.

Now open and lay bare the Roots of Trees that feem to languish, in order to take from about them the old Soil, cut off as much of their Roots as is found in an ill condition, and Earth them up again afterwards with good new Earth.

Make some Hot Beds for Mushrooms. The method to make them well, is to choose some spot of new. and as near as can be, light and fandy Ground, and dig there a hollow Bed of five or fix Inches deep, of three or tour wide throughout, and of what length you pleafe The Dung must be either of Horle or Mule, and must be already pretty dry, and such as has been piled up fome time: Then make the Bed about two foot high. ranking and preffing the Dung as close and tight as you can, yet so that it may the better shoot off the waters to the right and left, which if they will pierce through it, would rot the Dung; after that, cover the Bed to the thickness of two foot more, with the Neighbouring Earth, over which again, throw another covering of three or four Inches thick of Litter. which in the Winter may guard from the great Cold. and in the Summer, hade from the violent heat the Mushrooms which may be expected to shoot up about three or four Months after.

Employ the long dry Dung of which you ought to have made provision in the Summer, to cover your Fig Trees, as well those of the Wall, as Dwarfs; and for these last, tie all their Branches as close together as you can conveniently, with Ofter Withs, that you may the more eafily wrap them about with this covering; and for the Wall-Trees, endeavour to leave for many of the higher Branches as you can, on the fides, and to tie feveral of them together to poles or torked flicks that are to serve them for Props, and by that means, you cover them with more eafe,

and less charge. Leave on them that covering till the full Moon of March be past, at which time, only take off part of it, till the full Moon of April be likewise past. The Frosts of these two last Months being dangerous to the young Fruit which then begins to put forth it self, as the Winter Frosts are to the Wood which they make to turn all into Pith.

The days being now very short, skilful Gard'ners will therefore work by Candle-light till Supper time, either in making of Straw-Screens and Coverings, or preparing Trees for planting, as soon as the Frost per-

mits them, or in deligning, &c.

Put those Trees into the Earth in Furrows which you could not Plant, covering up the Rooss as carefully as if we were Planting them in their designed places, without leaving any hollow Chinks about their Rooss, because otherwise the great Frosts would spoil them.

You may begin at the latter end of the Month to force such Asparagus, as are at least three or four years old, and this forcing is performed, either on the cold Bed in the place where they grow, which is the best way, or else upon a Hot Bed, if you be minded to remove them. But ordinarily we stay till towards the beginning of the next Month, before we make any Essays of that kind, it being in my Opinion, long enough to have of them for four Months together by Artifice, till Nature be ready to surnish us with more of them for two Months longer by her own sole Virtue and Power, not but that we might begin to force them at the very beginning of September or Ostober.

The way of forcing them is, to dig the Earth out of a Path, to the depth of two Foot, and the breadth of one full foot and a half, if originally the Path were but three foot over, because there must at least six or seven good Inches of Earth be left next the Aspará-

gus Tufe. The Path being thus voided, we fill it up with long hot Dung, very well ramm'd and trodden down, till it be a full foot higher than the Superficies of the Cold Bed, at the first making, and after fifteen days. you must stir this Dung over again, mixing some new Dung with it, the better to enable it to communicate sufficient heat to the two adjoyning Cold Beds, but if it appear too much mortified, fo that the Asparagus does not shoot up briskly enough, then this recruiting the path-way with fresh Dung and stirring, must be repeated afterwards as often as it shall be necessary, which commonly happens to be once every ten or twelve days. If there fall any great Rains or Snow, that may have too much rotted that Dung, so that it appears not to retain a sufficient heat, then must it be quite taken away, and all new put in its place; for in fine, this Bed must always be kept extremely hot; as to the Cold Bed, in which the Plants are, the Ground must be digged up and firred a little in it, to the depth of about four or five Inches, as foon as the path-way is filled up, for it cannot be done before, because of bringing the Dung to that, (which cannot be done without much trampling on the Soil) which digging being finished, we cover the faid Cold Bed, with some of the same long Dung, to the thickness of three or four Inches, and at the end of fifteen days, so much time at least being necessary to give activity to those Asparagus Tusts, that in this Season are as 'twere dead, or at least benumbed with the cold, we lift up the Dung to fee whether the Asparagus begin to shoot out or no, and if they do, at every place where they appear, we clap a Glass Bell, which we also take great care to cover close with long Dung, and especially a-nights, to prevent the Frost from penetrating in the least to the Asparagus, which being so extremely tender and delicate as 'tis, would be absolutely spoiled by the least breath of Cold. If in the day time, the Sun thing

Thine out a little bright, we must not fail to take off the Dung from the Bells, that the Alparagus may be vilited by those kind Beams that animace all things, and if befides those Bells, we had likewise Glass Frames to clap over them, and so doubly to cover whole Beds of Plants. that would be still more commodious and more advantageous for bringing to effect this little Master piece of our Art. By these helps, the Asparagus springing out of the warm Earth, and meeting with a warm Air under those Bells, grow red and green, and of the same thickness and length as those of the Months of April and May: nav, and prove a great deal better too, because they have not only been unattack'd by the injuries of the Air, but have attained their perfection in much less time than the others, and I can without vanity affirm, that I was the first that by the inducement of some very plaulible Reasons, divised this expedient.

I add here, that a Bed of Affaragus dextroully forced and well maintained, produces abundantly for a fornight or three Weeks, and that because the King should not want during the whole Winter, this new Dish as soon as the first Beds begin to surnish us, I begin to force as many new ones, and so continue the same course every three Weeks, till the end of April, when Nature advertises me, that 'cis time to put an end to those Violences I have done Her, and that she is then willing in her Turn, to serve us with

fome Dishes prepared by her own skill.

You may likewise remove old Asparagus Plants out of Cold Beds into Hot ones, it being true that they spring there, but they never prove so rais as the others, and are attended besides with this inconvenience, that they die there in a very short time.

We force Sorrel and Wild Endive, or Succery, Massedonian Parsly or Alisanders, &c. in the same manner as we do Asparagus, but most commonly it is done

rather

rather upon Hot Beds, than on the naked Earth, and the Success is very speedy and infallible, and particularly in procuring in one fifteen days time, Sorrel that

is as fair as that of the Month of May.

We should have finished our last manuring of dry Grounds the sisteenth day of this Month, as well to render them impenetrable to the Rain and Snowwaters, as to destroy the Weeds, and to make our Gardens

appear something neat and handsome.

To have Radishes betimes, that is, towards Christmas, or Candlemas, we sow them in Hot Beds about the middle of November, I have already laid down directions for the making of Hot Beds, in the works of February: That which is particularly to be observed for Radishes. is that we must beat down with a board, the Superficies of the Mold, to render it a little folid, and to prevent it from rowling into the Holes that are to be made to Sow the Radifhes in, after which, that the Bed may be handsomely Sown, we take a Cord rubbed with Plastera or Chalk, or other white matter, and holding it well stretched out between two of us, we mark out with it as many white Lines, at three or four Inches distance one from another, both throughout the whole length and breadth of the Bed, as its extent will permit, and then with a round wooden planting stick of a full Inch thick, we make holes all along every Line at the like distance of three or four Inches one from another, and we put only three Radish Seeds into every Hole, and if we chance to let fall any more, we pull up all the Radiffies that come up above the number of three. They which observe not to mark out such Lines, but make their Holes by random-fight only, have their Beds not to hanfome, and they which make their Holes nearer, and which leave more than three Radishes in a Hole, run the hazard of having Radishes with a great many Leaves and but little Roos, There are many Markes X Gardners

Gard'ners whose practice it is, to sow Lines or Rows of Lettuces in February and March, a-cross their Beds of Radisches, but then the Holes must be made at the distance of seven or eight Inches; and the Lettuces thus sown in Lines, will be gathered and spent before

the Radishes are fit to gather.

If it treezes very hard we cover the Hot Beds, with long Litter, for five or fix days; befides which, for its farther defence against the rigours of the Winter, we cover them with Straw-Screens, or Coverings, supported upon Traverse Frames or Cradles composed of Stakes, or other Poles of Wood, placed very near the Superficies of the Mold, and we stop the sides close up, and if the Frost increase notably, we put a new Load of long Dung over those Straw-Screens; but if it be but moderate, there will need no other covering, the heat of the Bed being sufficient to defend the Plants; Radisses thus sown come up in five or fix days, and if the Holes had not some Air, they would be smoothed and grow dwindling in piercing through the small Straw.

We must not fail at the beginning of this Month, to take up in Turf, the Cellery which we had planted at a reasonable distance, in the Months of Juneand July, in particular Cold Beds; and when we have taken it up, to carry it into the Conservatory, or elle to replant it in some other Cold Bed, placing its Plants very close together, that they may the more easily be covered.

Ciacs, but n. ..

Provisions

Provisions and Products of November.

E have still in the beginning of the Month, some Figs, and some latter Tellow Pavies.

Winter Thorn Pears, Bergamots, Marchionesses, Messire Johns, Crasans, Petitoins, some Virgoulee Pears, Ambrets, Leschasseries, Amodots, &C.

Artichoaks.

Abundance of Autumnal Calvil Apples, and some

The Fenneless or Fennel Apples, and Courpendu's, or

hort stalk'd Apples begin also to ripen.

We have Spinage, Endive and Succory, Cellery, Lettuces, Sallers, and Pot Herbs, and Cabbages, of all forts, and Roots and Pumpions.

For Flowers we have almost the same as in the foregoing Month, as also some beginnings of Thiase

Semper virens, or ever green Thiaffis.

How to judge certainly by viewing and visiting a Kitchen-Garden, whether there be any thing wanting in it, which it should be stock d with in November.

THE first White Frosts of November that make the Leaves of Trees grow Yellow, and loosen them from the places where they grew, that shrivel up and rot the Leaves of Endive, and of the larger Lettuces, and that Blacken the Artichoke Tops, &c. give us warning of the approach of Winter that merciles Enemy of all Vegetations: and therefore we must take care early to secure in our Conservators or Store house, all that is liable to be spoiled by the Cold without-doors, and besides, to cover with long dry

Works to be done in December.

which must be generally of long Dung.

S soon as December is come it is no longer time to dally. For now the Barth in Gardens is quite stript of all its usual Ornaments, and the Frost that seldom sails to signalize it self this Month without respecting the quality of their Masters, spares no bodies Gardens, but unmercifully destroys all it meets with of a nature too delicate to endure its rigour; and therefore it concerns us now to make an end of housing and of covering what we could not house or

cover in the Month of November, viz. Endive, Cardons, Cellery, Artichokes, Roots, Collyslowers, Chard-Beets, Leeks, Fig Trees, &c. And above all things, we must be careful to preterve those Novelties which we may have begun to advance by Art, as Peas, Beans, Cabbage, Lettuce, and little Sallets, to avoid the displeasure of seeing perish in one bitter Night, what we have been labouring two or three Months to advance.

We may likewise still at the beginning of the Month, continue to sow some early Peas upon some Banks made of Earth raised in double slopes along by some Wall placed in a good Exposition, and especially

that towards the South.

We transport our rotten Dung to those places we design to muck and spread them abroad there, that the Rain and Snow waters may the better penetrate them, and carry their Salt a little below the Superficies of the Earth where our Seeds are to be sown.

One of the most principal Works of this Month, is, at the beginning of it, to make a Hot Bed of long new Dung of the ordinary breadth of four Foot, and height of three, and as foon as its great heat is spent, we must fow upon it, under Glass Bells, some good bright Curled Lettuce, and as soon as cis grown a little big, which usually happens in a Month's time, we must take up the fairest, and plant it in a Nursery upon another Hot Bed, and under other Bells, to the number of twenty, or twenty five under every Bell, and when they are grown reasonably big there too: we must take up the biggest with a little Earth about them to replant them, to the number of five or fix under each Bell, to remain there till they be quite Cabbage, which usually happens towards the latter end of March, and we take care to fence them well from the Cold, as well with Coverings of Litter, as by new heating their Beds.

X 3

We practife the same method in sowing these Lectuces in the Month of January, and in replanting in
February, that we may have some ready berimes, that
is, towards the end of March, and to continue so doing till the Earth produces us some of her self, without
the help of Hot Dung. At this time they that employ themselves in rearing Novelties, spend the most
part of each day in covering them at night, and uncovering them in the morning, or else all comes to no-

When in the Winter time, we are raising and forcing of Lettuce upon Hot Beds, and under Bells, we must be careful often to lift up the Bells, to take away the dead Leaves, there being a great many that rot and perish, and one rotten Leaf rots others. The inside of the Bells must also be cleansed from the filth and moisture that gather there in abundance, and when there comes a fair Sun shiny day, we must not fail to lift up the Bells, that the moisture may be dried up that sticks about the Leaves. But the che f. It thing to be observed above all, is to keep the Beds' moderately hot, by recruiting and new heating, and sermenting them from time to time.

Provisions and Products of December.

Y the affiltance of our Store-house and Conservatory, we have all the same things that we already mentioned in the Month of November.

We may also now begin to have some forced Aspa-

ragus ; And,

Some very green and tall Sorrel, in spite of the hardest Fros.

Spinage.

Winter Cabbages, as well of the bright and long sided fort, which are the most delicate, as of the green fort.

Abundance

Abundance of Virgoulee Pears, Thorn Pears, Ambrets, St. Germans, Dry Mertins, Portal Pears, &c. As also.

Of Api Apples, Pippins, Courpendu's, Fennellets or

Fennel Apples, and some Calvils to still &c.

As to Flowers we have store of Lawrel, Time, Flowers, and we have some Anemonies and Ciclamens.

How to judge certainly by viewing and visiting a Kitchen Garden, whether there be any thing wanting in it, which it should be stock a with in the Months of September and October.

THE Month of December, is still not without standing in need of a great deal of activity, for it often happens that the preceding Month proves too short to let us finish all that should be done in it, which must therefore be made an end of in this, and that particularly if the Cold have not yet made all the havock it is capable of: We must then mind exactly to do all I have directed to be done under the head of the Works of this Month: to prepare the Novelties of the following Spring; to clear the places of old Hot Beds, and to make preparation for the making of new ones with all imaginable expedition, and care taken, not only to have a good provision of long Dung, and a great many Glass-Bells, but likewise to keep all the Glass-Frames in good repair, &c. And here I shall not forget to recommend to those curious persons who are bleffed with the means to do it, to take care to force Asparagus, and to recruit their Beds with new warmth as often as their great heat shall begin to flag. It is a work indeed of no confiderable pains and expence, but the pleasure to see growing, in the midst of the severest Frost and Snow, abundance of Asparagus, both thick, green, and every way most excellent, is great enough to take us off from grudging at our cost or CHAP. trouble. XA

CHAP. V.

What fort of Ground is proper to each Legume and Kitchen Plant.

Here are certain forts of Grounds, which want none of the good Qualities required to make them produce in every Season, and for a long; time together, all forts of fair and good Legumes supposing always, that they be reasonably well cultivated: And there are some that besides that, have the faculty to produce them more early than others, and they are fuch Grounds as they commonly call Black Sands, in which is found an equal temper between dry and moist, accompanied with a good exposition, and with an inexhaustible Salt of fertility rendring them easie to be entred by the Spade, and penetrated by the Rain-waters: But on the other hand, it is rare enough to find any of these perfect forts of Earth; and that on the contrary, it is very usual to meet with those that offend either in being too dry, light, and parching, or over moift, heavy and cold, or elie by being ill fituated, as being some of them too high, some too floping, and some of them too low, and too much in a Bottom. Or more especially excessive moisture, and great drought are both pernicious, because this last, besides that it is always attended with a chilling Cold that retards its productions, is likewise apt to rot the greatest part of the Plants, and configuratly, it is very difficult to correct, and almost impossible entirely to furmount so great a defect; but it is not altogether so difficult to qualifie a dry temper, for provided it be not extreme great, and that we have the convenience of Water to water it, and of Dung to amend and enrich it, we are Masters of two Sove-Bilingia a a gi . . A see gien wie ih ihr reign

reign and infallible Remedies, which we must apply for its cure. And so by care and pains we may get the Conquest over those dry and stubborn Lands, and force them to bring forth in abundance all things we

shall regularly demand of them.

It tollows thence, that when we are so happy as to meet with those choice good forts of Ground, we may indifferently both fow and plant every where in them. any forts of Legumes or Plants whatfoever, with an affured Confidence, that they will prosper. The only Subjection we are obliged to in such Grounds is, first, to weed much, because they produce abundance of Weeds among the good Herbs; and secondly, to be often removing our Legumes and changing their places, which is an effential point of Practice in all forts of Gardens, it being not at all convenient to place for two or three times together, the same Vegetables in the same piece of Ground, because the Nature of the Earth requires these forts of Changes. as being as 'twere affured in this Diversity, to find wherewithal to recruit and perpetuate its first vigour And though in those good Grounds all things prosper admirably well, yet is it a most undoubted Truth, that Southern and Eastern Expositions are here as well as every where elfe, more proper than those of the West and North, to forward, and improve its productions: witness Strawberries, Hasting Peas; Cherries and Muscat-Grapes, &c. To balance which, these last Expofitions have likewife some peculiar advantages, that make them to be esteemed in their turn; for Example during the excessive Heats of Summer, that often scorch up every thing, and make our Legumes and other Plants run up too hastily to Seed, they are exempt from those violent impressions, which the Sun makes upon those places that are fully exposed to his burning Rays, and consequently our Plants will maintain themfelves longer in good plight in those situations than in the others.

It also follows from hence, that if any Person have Ground, though tolerably good, yet not of an equal goodness all over, either caused by the difference of its natural temper, or situation, and sloping inclination upwards or downwards, that then I say, the skill and Industry of the Gard'ner shews it self, by knowing how to allot every Plant the place in which it may best come to maturity in every Season, as well in regard of Forwardness, and sometimes of Backwardness, as of its outward Beauty, and inward persection.

Generally speaking, those Grounds that are moderately dry, light, and sandy, and such as though they be a little strong and heavy, situated on a gentle rising towards the South or West, and are backed by great Mountains, or senced by high Walls against the Cold Winds are more disposed to produce the Novelties of the Spring, than the strong, heavy, sat and moist Sands: but likewise on the other Hand, in Summers, when there salls but little Rain, these last produce thicker and better nourish Legumes, and require not such large and frequent Waterings, so that we may find some sort of Satisfaction in all sorts of Greunds.

However though absolutely speaking all things that may enter into a Kitchen-Garden, may grow in all forts of Grounds that are not altogether Barren; yet it has been observed in all times, that all forts of Earth agree not equally with all sorts of Plants; Our able Market Card'ners justifie the truth of this by a most convincing Experience; for we see that such of them whose Gardens are in Sandy Grounds, seldom mind to plant in them any Artichokes, Colly-stowers, Bees-Chards, Onions, Cardons, Cellery, Beet raves, or Red Beet Roots, and other Roots, &c. as those do that have theirs in stronger and more hearty Lands, and on the contrary, these last employ not their

Ground in Sorrel, Purstain, Lettuce, Endive, other small Plants that are delicate and subject to perish with Mildew, and the Wet rot, as do those whose Gardens are in

lighter Lands.

· From what has been faid, there refult two things = the first is, that an able Gard'ner which has a pretty dry and hilly Ground to cultivate with an Obligation to have of all forts of things in his Garden, should place in the moistest parts those Plants that require a little moisture to bring them to perfection, as Artichokes, Red Beet-Roots, Scor Zonera's, Sailifies, Carrots, Parinips, Skirrets, Beet-Chards, Colli flowers and Cabbages, Spinage, Common Peas, Beans, Currans, Goofeberries, Raspberries, Onions, Ciboules, Leeks, Partly, Sorrel, Radilbes, Patience or Dock Sorrel, Sweet Herbs, Borage, Bugloss, &c. And supposing the Provision above specified, be already planted in its other parts he should fill up the dryer parts of the same Garden with Lettuces of all Seasons, Endive, Succory, Chervil, Tarragon, Bafil, Burnet, Mint, and other Sallet Furnitures, and Purstain, Garlick, Shallots, Winter Cabbages, Hot Beds of all forts of Plants, and of little Sallets; and he must place his Legumes there at moderate distances, because they grow not of so large a Size and Stature there, as in fatter p'aces. And lastly, he must keep his Walks and Path ways higher than his dreffed Grounds, as well to draw into thete latter the Rain-waters that would be unuseful and incommodious in the Walks, is to render the artificial waterings he shall be obliged to use, of the greater advantage to them, by preventing them from running out any where aside, which must be one of his principal Applications.

He must also chuse out in the same Grounds those Parts which come the nearest to the good temper between dry and moist, for the raising of Asparagus Strawberries, Careons, Cellery, &c. because these sorts of Planes languish with drowth in places too dry, and

perish

perish with Rottenness in parts over-moist. He must place in the Border under his Northern Walls his Alleluia's, Latter Stramberries, and Bourdelais, or Verinice Grapes and in the Counter Borders of the same Noribern Quarter, he may make his Nursery Beds for Strawberries, and fow Cheruil all the Summer long, the North fide in all forts of Grounds, being most proper for those purposes. And as this Gard'ner should be curious of Novelties, he ought to look upon the Banks under the Walls towards the South and East to be a marvellous and favourable shelter for the railing them: as for Example, for the procuring of Strawberries and early Peas at the beginning of May, Violets at the entrance of March, and Cabbage Lettuces at the beginning of April. He should likewise plant in the dressed Banks next to the same Eastern and Western Walls. his Nursery of Cabbages, and low there his Winter Lettuces, that is, Shell-Lettuces, to remain there all Autumn and Winter, till in the Spring it be time to transplant them, into the places where they are to come to perfection: He should likewise plant in the Borders of the same Walls, his Fasse-phierre, or Sampire, which he can hardly have by any other means, which course is to be followed in all forts of Gardens; and in the Winter time he should likewise observé this parricular caution, to throw all the Snow off from the neighbouring places upon the dreffed Borders of those Wall trees, and especially those of the Eastern Quarter, both for the erecting a Magazine, as 'swere of Moisture in such places upon which the Rain but seldom falls, as upon those in which the violent heat of Summer is like to be of pernicious influence.

The second thing is, That the Gard'ner whose Garden is in a very fat and moist Ground, must take a quite contrary method with all his Planes to that just now above mentioned; always affuring himself that those parts of it which are very moid, unless he

can find means to drain and render them lighter; will be of no other use to him than to produce noxious Weeds, and confequently, that those which partake the least of that intemperature, whether by their own Nature and Situation, or by the care and industry of the ingenious Gard'ner, are always to be lookt upon as the best for all forts of things. He must place in the driest parts most of those Plants that keep in their places for leveral years together, excepting Currans, Goofeberries. and Raspberry Bushes; as for Example, Asparagus, Artichokes, Strawberries, Wild Endive and Succory, &c. In other places, let him put those things which in Summer require the least time to come to perfection, viz-Sallets, Peas, Beans, Radishes, nay and Chardons, Cellery, &c. and because all things grow thick and tall in those fat and moist places, therefore he must plant his Kitchen-planes there at greater distance one from the other, than in drier places; he must also keep his Beds and dressed Grounds raised higher, than his Walks and Pathways to help to drain out of his Grounds the Water that is so huriful to his Plants, and for that Reason, his Beds of Asparagus, especially as likewise his Stramberry and Cellery Bods, &c. no more than those of his Sallets must not be made Hollow, as those must be, that are made in drier Grounds: 5:15 to 35'10 ont probable (1 8. 10 Nicholas)

I have had good Success where the Ground is sat, viscous, and as twere Clayie, by railing in the midst of it, certain large Squares where the frequent Rain Waters in the Summer, of the Year 1682, remained without penetrating above seven or eight laches deep, and by having given to the said Squares by the means of that elevation, a sloping descent on each side, all along the bottom of which I made at the same time some little Dykes or water-courses about a soot deep as well to separate the Squares from the Counterborders as particularly to receive the mischievous Waters which by staying on the Squares, otherwise would

ruin all the Plants in them, which Waters afterwards discharged themselves into stone Gutters, which I had purposely ordered to be made to carry them off. I afrerwards raifed most of the Counterborders in the same manner. Arch-wife, that what water might remain in them, might shoot off into the sides of the Walks, all along which there were other little Dikes almost unperceivable, to receive those Waters and convey them into the fame stone Gutters; and I can truely affirm. that before I used this precaution, all that I had in those Squares, to perish the Planes with the Rot, and the Trees with the Jaundice; besides which mischiefs. the Winds easily threw up my Trees by the Roots, because they could hardly take any fast hold in that kind of Ground that was grown liquid and fost like new made Mortar, of Pap.

CHAP. VI.

What fort of Culture is most proper for every

particular Plant.

T is a very considerable Advance to have settled a Garden upon a good foot at first, and to have wisely employed; or at least assigned out all its parts according to the different Qualifications of its Gound, the goodness of its Expositions, the order of the Months, and the nature of each Plans: But that is not all, we must carefully cultivate them, in such a manner as

they peculiarly required

For there is a general Culture of Kitchen Gardens, and there is a particular Culture peculiar to each Plans. As to the general Culture it is well enough known, that the most necessary and important points of it consists first, in well mending and mucking the Earth, whether it be naturally good or not, because Kitchen Planes exhaust it much; secondly, in keeping it always loose and stirred, either by digging up whole Beds, to Sow or transplant in them. So, or such other places where the Spade

may be employ'd, as for Example among Artichokes. Cardons, &c. or by pecking and grubbing up where the closeness of the Planes to one another will permit us to use only grubbing Instruments, as for Example. among Stramberries, Lettuces, Endive, Peas, Beans, Cellery, &c. Thirdly in watering plentifully all forts of Plants in very Hot Weather, and especially in sandy Grounds, for those that are strong and rank require not fo much, always observing that in both forts of Ground, watering is not so necessary for Asparagus, nor for Borders or edgings of Time, Sage, Lavender, Hyllop. Rue. Worm-wood, &c. which need but little moissure to keep them in good plight. Fourthly, it confifts in keeping the Superficies of our Ground clear of all forts of Weeds, either by Weeding, or digging, or by only raking them over, when they have not been long dressed, so that as far as tis possible, the Earst may always appear as if it had been newly flirred up.

I shall not insist any longer here upon the Head of the General Culture, because it is so well known to all People, but shall only declare my Opinion and the practice of able Gard'ners in that which is peculiarly to

be used to each particular Plant.

I shall begin with observing to you, that among Kitchen Plants, there are some that are Sown to remain still in the place where they were first, and others again, only to be transplanted elsewhere; that there are some that prove well both wsys; some that are multiplied without Seed, some that are transplanted whole, and some that are cut to be transplanted, there are some which bear several times in a year, and that last longer than a year; others that produce but once in a year, but yet last to bear for several years after; and Lastly some again, that perish after their sirst production.

The Plants of the first Class, are Radiskes, almost all Red Beet-Roots, Carrots, Parsnips, Skirrets, Tunips,

Näches, Reponces, Scorzonera's. Salsifies, and besides them, Garlick, Chervil, Wild Endive, or Succory, Harts-Horn Sallet, Garden Cresses, Sallots, Spinage, Beras, small Lettuce to cut, Parsly, Burnet, Cutting Beets, Peas, Purslain, &c. and the greatest part of our Sorrel, Patience or Sharp-Leav'd Dock, Onions, and Ciboulees.

The Plants of the second Class which succeed not without being transplanted, are Chard Beets, Cellery, and the greatest part of our White Endive, both long and tied, and Cabbages, unless they be sown very thin, or be very much thinn'd after they are sown; of this Class are also Cabbages, most Musk melons, and Cucumbers, Citrulls or Pumpions, Potirons or flat Pumpions, Leeks, &cc.

Those of the third Class that is, such as may be indifferently either continued in the places where they are first sown, or transplanted elsewhere, are Asparagus, though most commonly they are sown at first in Nurseries, to be transplanted a year or two after; as also Basil, Fennel, Ansie, Borage, Bugloss, Cardons, Capucin Capers or Nasturces, Ciboulees, Savory, Time,

Musked Chervil, &cc.

The Plants of the fourth Class that are multiplied without being sown, are Alleluia, or Wood Sorrel, English Cives, Violets, &c. B. cause they grow into thick Tusts which are separated into many; Artichokes are propagated by their Eyes, Off sers, or Slips; Mint, and Round Sorrel, Tripe Madame, Tarragon, Balm, &c. by their Layers or Branches that take Root where they touch the Earth, the two last of which are multiplyed by Seed, as likewise are the Artichokes sometimes. Strawherries propagate by their Runners, Rasp berries, Gooseberries, and Currans, by their Slips, or Suckers, and by their Cuttings which also take root. Lavender, Worm wood, Sage, Time, and Marjoram, by their Branches which take Root at their joints, and are also multiplied by their Seeds

the common Bays, both by Layers and Seed too; Vines, and Fig Trees, by their Suckers, Hocked Slips,

and Cuttings, whether Rooted or not Rooted.

In the fifth place, those Plants of which we cut off some part either of the Leaves or Roots, or both at the same time, in order to transplant them, are Artichokes, Chard Beets, Leeks, Cellery, &c. As d these others whose Leaves we do not cut at all, though it be good always to Trim their Roots a little to refresh them, are Endive, and Succept, most commonly and Savey, Sorrel, &c. and all Lettuces, Alleluia or Wood Sorrel, Violets, Basil, Arrach or Orage, Borage, Bugloss, Capucin Copers or Nastunces, Cabbages, Tarragon, Samphire, Stramberries, Marjoram, Musk Melons, Cucumbers Citruls or Pumpions, Punsain, and Radishes for Seed, &c.

The Plants that bring forth several times in a year, and yet last sorrel, Partience or Sharp Dock, Alleluia or Wood Sorrel, Burnet, Chervil, Parsty, Fennel, all Edging, or Sweet Herbs, Wild Endive or Success, Macedonian Parsty of Alisanders.

Mint, Tarragon, Samphire, &c.

Those that produce but once in the year, but yet last bearing for several years together asterwards, are

Asparagus, and Arrichikes.

And lastly, those that cease to be useful after their first production are all Lettuces, Common Endive, Peas, Beans, Cardons, Melons, Cucumbers, Citruls or Pumpions, Onions, Leeks, Cellery, Arrach or Orage. and all Plants whose Roots are only in use, as Red Beets, Carrots, &c.

Now to give you a particular account of the Culture that belongs to every feveral fort of Plant, I must tell you, that this Culture confilts, first, in observing the distances they are to be placed at one from the other; second, in the Triming of such as need it; third, in planting them in that situation, and disposition which they require; fourth, in giving them those assistances

which some of them have need of to bring them to perfection, or which are convenient for them, whether it be by tying up, or wrapping about, or Earthing up, or otherwise covering them, &c.

CHAP. VII.

Shewing how long every Kitchen-Plant may profitably stand in its place in a Kitchen Garden; which of them must be housed in the Conservatory to supply us in the Winter, and which are they which we may force to grow by Art, in spite of the Frost. And lastly, how long each fort of Seed will last without losing its Vertue.

how long every Plane may usefully possess the place where it grows in our Gardens, that so the forecast of an able Gardner may prepare others immediately to substitute in the places of such, as being as 'twere but Passer gers, take up their places but a few Months; for by this means, not only there remains no unprofitable spot of Ground in our Gardens, but we seem besides to reap a sensible pleasure, by enjoying in some Sense beforehand some things that are not yet in Nature.

To treat of this matter well, I think it very pertinent to speak first of those Plants that are of long duration, whether in respect of the time they take up in attaining to their Persection, or of that in which they continue bearing. Asparagus, doubtless, hold the first Rank in this number, and as to Asparagus, reckoning from the time we first sow or transplant them, we ought hardly ever to begin to gather them till their shoots be of a competent thickness, which

which happens not till the third or fourth year after, but after that time, provided they be placed in good Ground, and carefully cultivated, they may very well be fuffered to ftand ten or twelve years, it being certain that they will not fail to fhoot up and bear vigorously and plentifully during all that time; but yet if we perceive any decay in them sooner, we may deftroy and break them up sooner; and if on the contrary, we find them continue to produce well longer than we have limited, we may continue them longer in their places.

Rasberry, Curran, and Gooseberry shrubs, easily last

eight or ten years.

Areichokes must be renewed, that is, new planted in

a fresh place after the third year.

The Borders of Wormwood, Hysop, Lavender, Marjoram, Rue, Rosemary, Sage, Time, Violets, &c. provided they be not endamaged, by an extraordinary hard Winter, may subsist in their places three or four years, if care be taken to clip them pretty close every Summer.

Alleluia, or Wood-forrel, Mint, Musked Chervil, English Cives, Tarragon, Sorrel, Patience, or sharp Dock, Samphire, Macedonian Parsly or Alisanders, Trip Madame, &c. may likewise last well enough in their places three

or four Years.

Strawberry Plants may last three years, Wild Endiwe or Success, Anis, Ordinary Parsly, Burnet, Fennel, Scozonere, and Common Salsisses, &c. last two years.

Leeks both to cut, and for Chards, and Cibeuls, &c.

last a year, that is, from one Spring to another.

Borage, Buglos, Red Beet Roots, Spanish Cardons, Carrots, Skirrets, Cabbages, Milan Cabbages, Colliflowers, Citruls or Pumpions, Harts-horn Sallet, Potitions or Flat Pumpions, Parsnips, Leeks, &cc. keep their places nine Months, that is, reckoning from the Spring, when they were sown, to the end of Autumns

Y 2 Garlick

Garlick, Basil, Nasturces or Capucin Capers, Cucumbers, and Melons or Muskmelons, Shalots, Onions, and the first or Summer Turneps. &c. teke them up only during the Spring and Summer Seasons, so that their places may receive a new Decoration of Plants in Autumn.

Arrach, or Orage, Ordinary Chervil, White Endive, and Succory, Garden Creffes, and all forts of Lettuces, whether to cabbage, or to the up, So take up the r Ground about two Months.

Radishes, Purstain, and Ordinary Chervil, &c. take up their places but five or fix Weeks, and therefore they must be new sown every fifteen days in Summer time.

Hasting Pease and Beans, continue on the Ground fix or Even Months, reckening from the Month of November when they are sown; but common Pease and Beans, and Aricos, or French-Beans, take it up but four or five Months.

Spinage and Mâches keep theirs all Autumn and Winter and therefore are planted in places where we have already raised such Plants as last not beyond the Summer.

Mallows and Marsh-malows are multiplyed only by

Seed, and pass not beyord the Winter.

The Plants that require housing in the Conservatory during the Winter, are Cardoons, Cellery, Artichoke keads, both the Endiv.s. as well the White, as the Wild fort; all that are known by the name of Roots, as Red Beet Roos, Carrots, &c. as likewise Leeks, Cetruls or Pumpions, Potirons or Common Pumpions, Garlick, and Shalots All the rest result the injuries of the Winter well enough, viz. Cabbages, Parsty, Fennel, Cibouls, and even Tarragon, Mint, Samphire, Trip-Madam, Balm, Asparagus, Sorrel, &c. But they sprout not till the Spring, unless forced on Hot Beds. Other Plants are not acquainted with that sort of help, or rather Violence, such as are all Roots, and

Garlick, Onions, Leeks, Cabbages, &c. Add to this, that by the same expedient of Hot Beds we may also raise in the height of cold Weather, little Sallets of Lettuces, with their Furnitures of Cresses, Chervil, Mint, &c.

There remains now nothing but to know how long each fort of Seed will keep good; upon which I must tell yeu; that generally speaking, most Seeds grow nought after one or two years at most, and therefore it concerns us always to be provided with new ones. if we would not run the hazard of fowing to no purpose in the Spring. There are hardly any but Pease. Beans, and the Seeds of Muskmelons, Cucumbers, Citruls or Pumpions, and Potirons or Flat Cucumbers. that last eight or ten years. The Seeds of Collistowers last three or four, and those of all forts of Endive and Succory, five or fix years. Of all forts of Seeds there are none that keep so small a time as Lettuce Seed. which yet are better the second, than the first year, but yet are good for nothing the third. Concerning which, with the Particular Culture of each several Plane, and the Monthly Provision and Products both of Fruits and Plants, See the Alphabet, Page 175.
